

Statistics 582, Problem Set 3 Solutions

Wellner; 1/31/2007

1. We showed in class that the nonparametric maximum likelihood estimator of F in the (right) censored data problem, possibly with ties, is the Kaplan-Meier (product limit) estimator $\widehat{\mathbb{F}}_n(t)$ given by

$$1 - \widehat{\mathbb{F}}_n(t) = \prod_{s \leq t} (1 - \Delta \widehat{\Lambda}_n(s))$$

where $\widehat{\Lambda}_n(t)$ is the *Nelson-Aalen* estimator of

$$\Lambda(t) \equiv \Lambda_F(t) \equiv \int_0^t \frac{1}{1 - F_-} dF,$$

given by

$$\widehat{\Lambda}_n(t) = \int_0^t \frac{1}{1 - \mathbb{H}_n(s-)} d\mathbb{H}_n^{uc}(s) \quad 0 \leq s \leq t.$$

Here

$$\mathbb{H}_n^{uc}(t) = \frac{1}{n} \sum_{i=1}^n \delta_i 1_{[Z_i \leq t]}, \quad \mathbb{H}_n(t) = \frac{1}{n} \sum_{i=1}^n 1_{[Z_i \leq t]}$$

are the sub-empirical distribution function of the uncensored observations and the marginal empirical distribution of all the Z 's uncensored or censored.

A. Compute $1 - \widehat{\mathbb{F}}_n$ for the following data (time in days until vaginal cancer in rats, group 1; from Kalbfleisch and Prentice, 1980, page 2):

143, 164, 188, 188, 190, 192, 206, 209, 213, 216,
220, 227, 230, 234, 246, 265, 304, 216+, 244+

here + indicates censoring ($\delta = 0$).

B. In class I gave a heuristic derivation of

$$\sqrt{n}(\widehat{\mathbb{F}}_n(t) - F(t)) \Rightarrow (1 - F(t))\mathbb{B}(C(t))$$

as a process uniformly in $t \in [0, \tau]$ for any $\tau < \tau_H$ (i.e. for any τ with $1 - H(\tau) = (1 - F(\tau))(1 - G(\tau)) > 0$, where \mathbb{B} is a standard Brownian motion process and where

$$C(t) \equiv \int_0^t \frac{1}{(1 - H_-(s))^2} dH^{uc}(s), \quad 0 \leq s \leq t$$

Thus we have, for each fixed $t < \tau$,

$$\sqrt{n}(\widehat{\mathbb{F}}_n(t) - F(t)) \rightarrow_d N(0, (1 - F(t))^2 C(t))$$

Suggest an estimator of $C(t)$ and hence an estimator of $(1 - F(t))^2 C(t)$.

C. Show that your estimator of $(1 - F(t))^2 C(t)$ is consistent.

D. Use the estimator you suggest in B to obtain an approximate 90% confidence interval for $F(200)$ based for the data given in A.

Solution: A. In this case there are ties in the data, just as in problem 2 below. Here is a table giving the distinct time points T_i together with the numbers at risk and the number of deaths at each time point, together with the successive terms of the product and the resulting Kaplan-Meier estimator. The last two columns of the table give two variance estimates: column 6 gives the variance estimator from problem B; column 7 gives the usual Greenwood estimator (cf. part D below and Kalbfleisch and Prentice (1980), pages 12 - 14).

Table 1:

T_i	r_i	d_i	$1 - \frac{d_i}{r_i}$	$\prod_{j \leq i} (1 - \frac{d_j}{r_j})$	$\widehat{Var}(\widehat{F})$	$\widehat{Var}_{GW}(\widehat{F})$
143	19	1	18/19	.9474	.00249	.00262
164	18	1	17/18	.8947	.00469	.00496
188	17	2	15/17	.7895	.00796	.00875
190	15	1	14/15	.7368	.00935	.01021
192	14	1	13/14	.6842	.01045	.01137
206	13	1	12/13	.6316	.01126	.01225
209	12	1	11/12	.5789	.01179	.01283
213	11	1	10/11	.5263	.01204	.01312
216	10	1	9/10	.4737	.01199	.01312
220	8	1	7/8	.4145	.01187	.01311
227	7	1	6/7	.3553	.01129	.01264
230	6	1	5/6	.2961	.01028	.01170
234	5	1	4/5	.2368	.00882	.01029
244	4	0	1	.1579	.00882	.01029
246	3	1	2/3	.1579	.00669	.00873
265	2	1	1/2	.0789	.00323	.00530
304	1	1	0	.0000		

B. A natural estimator of

$$C(t) = \int_{[0,t]} \frac{1}{(1 - H(s-))^2} dH^{(uc)}(s)$$

is

$$\begin{aligned}\hat{C}_n(t) &= \int_{[0,t]} \frac{1}{(1 - \mathbb{H}_n(s-))^2} d\mathbb{H}_n^{(uc)}(s) \\ &= n \int_{[0,t]} \frac{1}{R_n(s)^2} d(n\mathbb{H}_n^{(uc)}(s))\end{aligned}$$

where $R_n(s) \equiv n(1 - \mathbb{H}_n(s-))$. Note that in the Mathematica program accompanying the solution set the quantity labeled ‘‘Cest’’ is $n^{-1}\hat{C}_n(t) = \int_{[0,t]} R_n(s)^{-2} d(n\mathbb{H}_n^{(uc)}(s))$.

C. To see that $\hat{C}_n(t) \rightarrow_p C(t)$ note that

$$\|\mathbb{H}_n^{(uc)} - H^{(uc)}\|_\infty = \sup_{0 < t < \infty} |\mathbb{H}_n^{(uc)}(t) - H^{(uc)}(t)| \rightarrow_{a.s.} 0, \quad (1)$$

$$\|\mathbb{H}_n - H\|_\infty = \sup_{0 < t < \infty} |\mathbb{H}_n(t) - H(t)| \rightarrow_{a.s.} 0 \quad (2)$$

by the Glivenko-Cantelli theorem.

$$\begin{aligned}\hat{C}_n(t) - C(t) &= \int_{[0,t]} \frac{d\mathbb{H}_n^{(uc)}(s)}{(1 - \mathbb{H}_n(s-))^2} - \int_{[0,t]} \frac{dH^{(uc)}(s)}{(1 - H(s-))^2} \\ &= \int_{[0,t]} \left(\frac{1}{(1 - \mathbb{H}_n(s-))^2} - \frac{1}{(1 - H(s-))^2} \right) d\mathbb{H}_n^{(uc)}(s) \\ &\quad + \int_{[0,t]} \frac{1}{(1 - H(s-))^2} d(\mathbb{H}_n^{(uc)}(s) - H^{(uc)}(s)) \\ &= \int_{[0,t]} \frac{(1 - H(s-))^2 - (1 - \mathbb{H}_n(s-))^2}{(1 - \mathbb{H}_n(s-))^2(1 - H(s-))^2} d\mathbb{H}_n^{(uc)}(s) \\ &\quad + \int_{[0,t]} \frac{1}{(1 - H(s-))^2} d(\mathbb{H}_n^{(uc)}(s) - H^{(uc)}(s)) \\ &= \int_{[0,t]} \frac{[(1 - H(s-)) - (1 - \mathbb{H}_n(s-))][(1 - H(s-) + (1 - \mathbb{H}_n(s-))]}{(1 - \mathbb{H}_n(s-))^2(1 - H(s-))^2} d\mathbb{H}_n^{(uc)}(s) \\ &\quad + \int_{[0,t]} \frac{1}{(1 - H(s-))^2} d(\mathbb{H}_n^{(uc)}(s) - H^{(uc)}(s)) \\ &\equiv I_n(t) + II_n(t)\end{aligned}$$

where

$$\begin{aligned}|I_n(t)| &\leq 2 \frac{\sup_{0 < s \leq t} |\mathbb{H}_n(s-) - H(s-)|}{(1 - \mathbb{H}_n(t-))^2(1 - H(t-))^2} \int_{[0,t]} d\mathbb{H}_n^{(uc)}(s) \\ &\leq 2 \frac{\sup_{0 < s \leq t} |\mathbb{H}_n(s-) - H(s-)|}{(1 - \mathbb{H}_n(t-))^2(1 - H(t-))^2} \cdot 1 \\ &\rightarrow_{a.s.} 0 \cdot \frac{1}{(1 - H(t-))^4} \cdot 1 = 0\end{aligned}$$

if $1 - H(t-) > 0$ by (2). Also,

$$\begin{aligned} |II_n(t)| &\leq \left| \int_{[0,t]} \frac{1}{(1 - H(s-))^2} d(\mathbb{H}_n^{(uc)}(s) - H^{(uc)}(s)) \right| \\ &= \left| n^{-1} \sum_{i=1}^n \left\{ \frac{\Delta_i 1_{[0,t]}(Z_i)}{(1 - H(Z_i-))^2} - E \left(\frac{\Delta 1_{[0,t]}(Z)}{(1 - H(Z-))^2} \right) \right\} \right| \\ &\xrightarrow{a.s.} 0 \end{aligned}$$

by the strong law of large numbers where we again use $1 - H(t-) > 0$. Thus $|\hat{C}_n(t) - C(t)| \leq |I_n(t)| + |II_n(t)| \xrightarrow{a.s.} 0$. Assuming that $1 - \hat{F}_n(t) \xrightarrow{p} 1 - F(t)$ this yields

$$(1 - \hat{F}_n(t))^2 \hat{C}_n(t) \rightarrow_p (1 - F(t))^2 C(t).$$

D. A 90% confidence interval for $F(200)$ is given by

$$\hat{F}_n(200) \pm z_{.95} n^{-1/2} (1 - \hat{F}_n(200))^2 \sqrt{\hat{C}_n(200)}.$$

where $P(N(0, 1) > z_{.95}) = .05$. For the data given I compute $1 - \hat{F}_n(200) = .6842$, $n^{-1} \hat{C}_n(200) = .0223$, and hence an approximate 90% confidence interval for the point estimator $\hat{F}_n(200) = 1 - .6842 = .3158$ is given by

$$0.3158 \pm 1.64485(.6842)(.0223)^{1/2} = 0.3158 \pm 0.1681 = (0.1477, 0.4839). \quad (3)$$

It turns out that the variance estimator based on \hat{C}_n is *not* the usual one for the Kaplan-Meier estimator: instead the usual Greenwood formula for estimation of $C(t)$ is

$$\hat{C}_n^{GW}(t) = \int_{[0,t]} \frac{d\mathbb{H}_n^{(uc)}(s)}{(1 - \mathbb{H}_n(s-))(1 - \mathbb{H}_n(s-) - \Delta\mathbb{H}_n^{(uc)}(s))}.$$

This yields $n^{-1} \hat{C}_n^{GW}(200) = 0.0243$ and the resulting value of $\widehat{Var}_{GW}(\hat{F}_n(t))$ at $t = 200$ is .01137 (rather than $.6842^2 \cdot .0223 = .01045$ as in (3)). This leads to the slightly different confidence interval

$$.3158 \pm 1.64485(.6842)(.0243)^{1/2} = .3158 \pm 0.1754 = (0.1404, 0.4912). \quad (4)$$

See Kalbfleisch and Prentice page 15 for a brief discussion of alternatives involving transformations to stay in the range $[0, 1]$ and to improve the normal approximation.

2. Consider nonparametric maximum likelihood estimation of F in the right-censored data problem considered in class, but extend the argument to include ties as follows:

A. When there are ties, let the distinct Z 's be denoted by $T_1 < \dots < T_k$. Let m_1, \dots, m_k and n_1, \dots, n_k be defined by $m_j \equiv \#$ of $Z_i \delta_i = T_j$, $n_j \equiv \#$ of $Z_i(1 - \delta_i) = T_j$, and let $p_j \equiv \Delta F(T_j) = F(T_j) - F(T_j-)$, $j = 1, \dots, k$, $p_{k+1} = 1 - F(T_k)$. Show that the likelihood (for F) is

$$L(F|\underline{Z}, \underline{\delta}) = \prod_{i=1}^k p_i^{m_i} \left(\sum_{j=i+1}^{k+1} p_j \right)^{n_i}.$$

B. By defining $\lambda_i = p_i / \sum_{j=i}^{k+1} p_j$ for $i = 1, \dots, k$ and $\lambda_{k+1} = 1$, and rewriting the likelihood in terms of the λ_i 's, show that the likelihood is maximized by

$$\hat{\lambda}_i = m_i / \sum_{j=i}^k (m_j + n_j) = \frac{n \Delta \mathbb{H}_n^{uc}(T_i)}{n(1 - \mathbb{H}_n(T_i-))}.$$

and hence that the nonparametric MLE of F is (again) the Kaplan - Meier estimator

$$1 - \hat{F}_n(t) = \prod_{s \leq t} (1 - \Delta \hat{\Lambda}_n(s)).$$

C. Compute $1 - \hat{F}_n$ for the following data (length of time until complete remission in weeks for the "maintained group") from a study of the efficacy of chemotherapy for acute Myelogenous leukemia (AML):

9, 13, 13+, 18, 23, 28+, 31, 31, 34, 45+, 48, 161+;

here "+" indicates censoring ($\delta = 0$).

Solution: When there are ties, let the distinct Z 's be denoted by $T_1 < \dots < T_k$. Let m_1, \dots, m_k and n_1, \dots, n_k be defined by $m_j = \#\{i \leq n : Z_i \Delta_i = T_j\}$, $n_j = \#\{i \leq n : Z_i(1 - \Delta_i) = T_j\}$, and let $p_j \equiv \Delta F(T_j)$, $j = 1, \dots, k$, $p_{k+1} = 1 - F(T_k)$. Then the likelihood (for F) is

$$L(F|\underline{Z}, \underline{\delta}) = \prod_{i=1}^k p_i^{m_i} \left(\sum_{j=i+1}^k p_j \right)^{n_i}.$$

Setting $\lambda_i \equiv p_i / \sum_{j=i}^{k+1} p_j$, $\lambda_{k+1} = 1$ yields

$$\sum_{j=i}^{k+1} p_j = \prod_{j=1}^{i-1} (1 - \lambda_j), \quad 1 - \lambda_j = \frac{\sum_{j=i+1}^{k+1} p_j}{\sum_{j=i}^{k+1} p_j},$$

and hence

$$\begin{aligned}
L(F|\underline{Z}, \underline{\Delta}) &= \prod_{i=1}^k \left(\frac{p_i}{\sum_{j=i}^{k+1} p_j} \right)^{m_i} \left(\sum_{j=i}^{k+1} p_j \right)^{m_i} \left\{ \frac{\sum_{j=i+1}^{k+1} p_j}{\sum_{j=i}^{k+1} p_j} \sum_{j=i}^{k+1} p_j \right\}^{n_i} \\
&= \prod_{i=1}^k \lambda_i^{m_i} (1 - \lambda_i)^{n_i} \left(\sum_{j=i}^{k+1} p_j \right)^{m_i+n_i} \\
&= \prod_{i=1}^k \lambda_i^{m_i} (1 - \lambda_i)^{n_i} \left(\prod_{j=1}^{i-1} (1 - \lambda_j) \right)^{m_i+n_i} \\
&= \prod_{i=1}^k \lambda_i^{m_i} (1 - \lambda_i)^{n_i + \sum_{j=i+1}^k (m_j + n_j)} \\
&= \prod_{i=1}^k \lambda_i^{m_i} (1 - \lambda_i)^{r_i - m_i}
\end{aligned}$$

where $r_i \equiv \sum_{j=i}^k (m_j + n_j)$. In view of the binomial form of this expression for each i , we know that it is maximized for each i by

$$\hat{\lambda}_i = \frac{m_i}{r_i} = \frac{m_i}{\sum_{j=i}^k (m_j + n_j)} = \frac{n \Delta \mathbb{H}_n^{(uc)}(T_i)}{n(1 - \mathbb{H}_n(T_i^-))},$$

for $i = 1, \dots, k$. Then

$$\hat{p}_i = \prod_{j=1}^{i-1} (1 - \hat{\lambda}_j) \hat{\lambda}_i, \quad i = 1, \dots, k+1.$$

as before. Note that $\hat{p}_{k+1} > 0$ if $n_k > 0$. Thus the nonparametric MLE's $\hat{\Lambda}_n$ and \hat{F}_n of Λ and F are the Nelson-Aalen and Kaplan-Meier (or product-limit) estimators

$$\hat{\Lambda}_n(t) = \int_{[0,t]} \frac{d\mathbb{H}_n^{(uc)}(s)}{1 - \mathbb{H}_n(s-)}$$

and $1 - \hat{F}_n(t) = \prod_{s \leq t} (1 - \Delta \hat{\Lambda}_n(s))$. For the given AMP data, the distinct times T_i are 9, 13, 18, 23, 28, 31, 34, 45, 48, 161. If we let $r_i \equiv n \mathbb{H}_n(T_i)$ and $d_i = n \Delta \mathbb{H}_n^{(uc)}(T_i)$ then we obtain the following table and calculated values of the estimator:

Table 2:

T_i	r_i	d_i	$1 - \frac{d_i}{r_i}$	$\prod_{j \leq i} (1 - \frac{d_j}{r_j})$
9	12	1	11/12	.917
13	11	1	10/11	.833
18	9	1	8/9	0.741
23	8	1	7/8	0.648
28	7	0	1	0.648
31	6	2	2/3	0.432
34	4	1	3/4	0.324
45	3	0	1	0.324
48	2	1	1/2	0.162
161	1	0	1	0.162

3. 4. (Interval censored or current status data). Suppose that X_1, \dots, X_n are i.i.d. random variables (survival times) with distribution function F as in Example 4.6.5. Suppose that Y_1, \dots, Y_n are i.i.d. random variables (“observation times”) with a distribution function G which are independent of the X_i ’s. Unfortunately, we cannot observe the X_i ’s directly but can only observe $(Y_i, 1_{[X_i \leq Y_i]}) \equiv (Y_i, \delta_i)$, $i = 1, \dots, n$.

A. Consider the empirical functions

$$\mathbb{G}_n(t) = n^{-1} \sum_{i=1}^n 1\{Y_i \leq t\} = \mathbb{P}_n 1\{Y \leq t\},$$

$$\mathbb{V}_n(t) = n^{-1} \sum_{i=1}^n \delta_i 1\{Y_i \leq t\} = \mathbb{P}_n \delta 1\{Y \leq t\}.$$

Show that for each fixed t we have

$$\mathbb{G}_n(t) \rightarrow_{a.s.} G(t), \quad \text{and} \quad \mathbb{V}_n(t) \rightarrow_{a.s.} \int_0^t F dG \equiv V(t).$$

B. Plot the cumulative sum diagram $\{(n\mathbb{G}_n(T_{(i)}), n\mathbb{V}_n(T_{(i)})) : i = 1, \dots, n\}$ and the MLE \hat{F}_n of F as described in example 4.6.5, page 38 of the notes, for the following data: $(3.5, 0)$, $(1.2, 1)$, $(5.7, 1)$, $(6.1, 0)$, $(4.2, 1)$.

C. What would the MLE of F be (at $t = 2$) if we assumed that F is exponential θ distribution (with $1 - F_\theta(x) = \exp(-\theta x)$ for $x > 0$)? Compare with the value of the MLE $\hat{F}_n(2)$.

Solution: A. By the Glivenko-Cantelli theorem we have $\|\mathbb{G}_n - G\|_\infty = \sup_{t > 0} |\mathbb{G}_n(t) -$

$G(t) \rightarrow_{a.s.} 0$, and $\|\mathbb{V}_n - V\|_\infty = \sup_{t>0} |\mathbb{V}_n(t) - V(t)| \rightarrow_{a.s.} 0$ where

$$\begin{aligned} V(t) &= E\delta 1\{Y \leq t\} = E\{E[\delta 1\{Y \leq t\} | Y]\} = E\{1\{Y \leq t\} E[\delta | Y]\} \\ &= E\{1\{Y \leq t\} F(Y)\} = \int_{[0,t]} F(y) dG(y). \end{aligned}$$

Thus, in particular, the pointwise convergences hold as claimed.

B. Here is a table of the observed values, the corresponding cumulative sum diagram, and the estimator at the observed points:

Table 3:

i	1	2	3	4	5
$Y_{(i)}$	1.2	3.5	4.2	5.7	6.1
$\Delta_{(i)}$	1	0	1	1	0
$n\mathbb{G}_n(Y_{(i)})$	1	2	3	4	5
$n\mathbb{V}_n(Y_{(i)})$	1	1	2	3	3

The following figures show the cumulative sum diagram and the resulting estimator of the df F .

Figure 1: Cumulative Sum Diagram.

Figure 2: Maximum Likelihood Estimator \hat{F}_n of F

C. If we assume a parametric model for F , namely the exponential distribution $F_\theta(x) = 1 - \exp(-\theta x)$, then the likelihood is

$$\begin{aligned} L(\theta|\underline{Y}, \underline{\Delta}) &= \prod_{i=1}^n F_\theta(Y_i)^{\delta_i} (1 - F_\theta(Y_i))^{1-\delta_i} g(Y_i) \\ &= \prod_{i=1}^n (1 - e^{-\theta Y_i})^{\delta_i} e^{-\theta Y_i \delta_i} \cdot \text{a factor depending on } g \end{aligned}$$

For the given data the likelihood is

$$L(\theta) = (1 - e^{-1.2\theta})(1 - e^{-4.2\theta})(1 - e^{-5.7\theta})e^{-3.5\theta}e^{-6.1\theta}$$

Use of a numerical maximization routine (I used Mathematica) yields $\hat{\theta} = 0.21033$, and this gives $\hat{F}_{parametric}(2) = 1 - \exp(-2(.21033)) = .343$. This should be compared to the nonparametric estimator at $t = 2$ which is $\hat{F}_n(2) = 1/2$.
