

2. Graphics in R

Thomas Lumley Ken Rice

Universities of Washington and Auckland

São Paulo, January 2014

Graphics

R can produce graphics in many formats, including:

- on screen
- PDF files for LATEX or emailing to people
- PNG or JPEG bitmap formats for web pages (or on non-Windows platforms to produce graphics for MS Office). PNG is also useful for graphs of large data sets.
- On Windows, metafiles for Word, Powerpoint, and similar programs

Setup

Graphs should usually be designed on the screen and then may be replotted on eg a PDF file (for Word/Powerpoint you can just copy and paste)

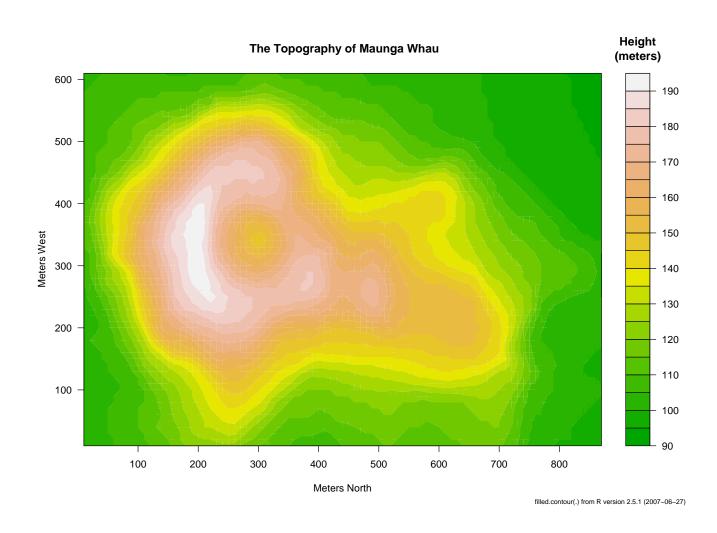

For printed graphs, you will get better results if you design the graph at the size it will end up, eg:

```
## on Windows
windows(height=4,width=6)
## on Unix
x11(height=4,width=6)
```

Word or LATEX can rescale the graph, but when the graph gets smaller, so do the axis labels...

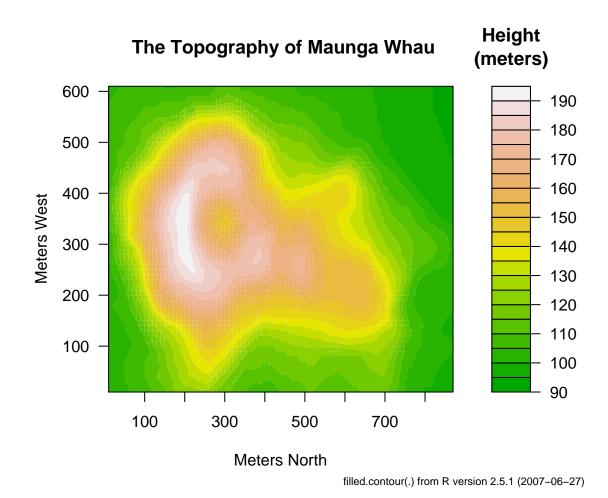

Setup

Created at full-page size (11×8.5 inches)

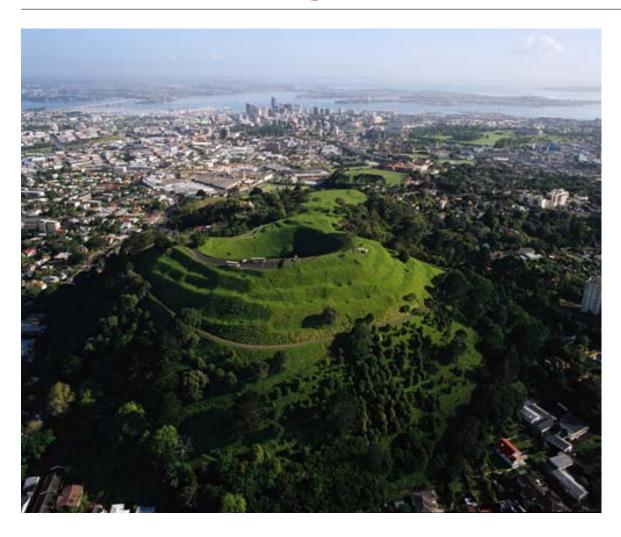

Better scaling

Created at 6×5 inches

The real thing

http://www.teara.govt.nz/en/photograph/3920/maungawhau-mt-eden

Finishing

After you have the right commands to draw the graph you can produce it in another format: eg

```
## start a PDF file
pdf("picture.pdf",height=4,width=6)
## your drawing commands here
...
### close the PDF file
dev.off()

You may find dir(), getwd() and setwd() helpful
```

Drawing

Usually, use plot() to create a graph and then lines(), points(), legend(), text(), rect(), segments(), symbols(), arrows() and other commands to annotate it. There is no 'erase' function, so keep your commands in a script.

plot() is a generic function: it does appropriate things for different types of input

```
## scatterplot
plot(salary$year, salary$salary)
## boxplot
plot(salary$rank, salary$salary)
## stacked barplot
plot(salary$field, salary$rank)
```

and others for other types of input.

Formula interface

The plot() command can also be used this way;

plot(salary~rank, data=salary)

where we introduce the formula system, that is also used for regression models. Here, think of $Y \sim X$.

The variables in the formula are automatically looked up in the data = argument.

Designing graphs

Two important aspects of designing a graph

- It should have something to say
- It should be legible

Having something to say is *your* problem; software can help with legibility.

Designing graphs

Important points

- Axes need labels (with units, large enough to read)
- Color can be very helpful (but not if the graph is going to be printed in black and white).
- Different line or point styles usually should be labelled.
- Points plotted on top of each other won't be seen

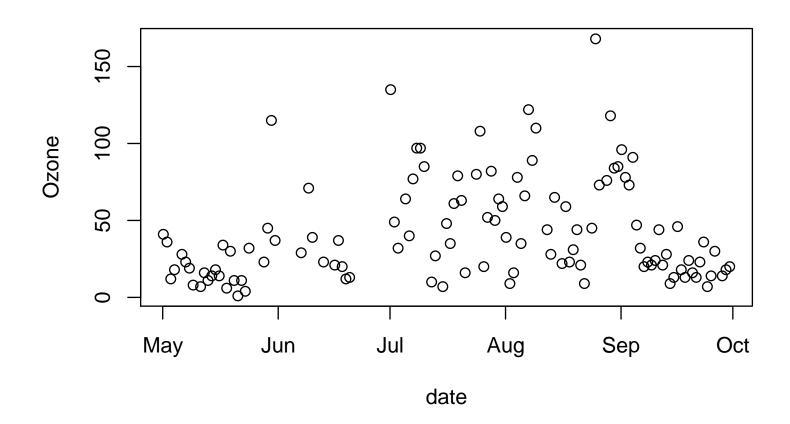

After these are satisfied, it can't hurt to have the graph look nice.

First we set up the data — in this case, a built-in dataset, containing daily ozone concentrations in New York, summer 1973

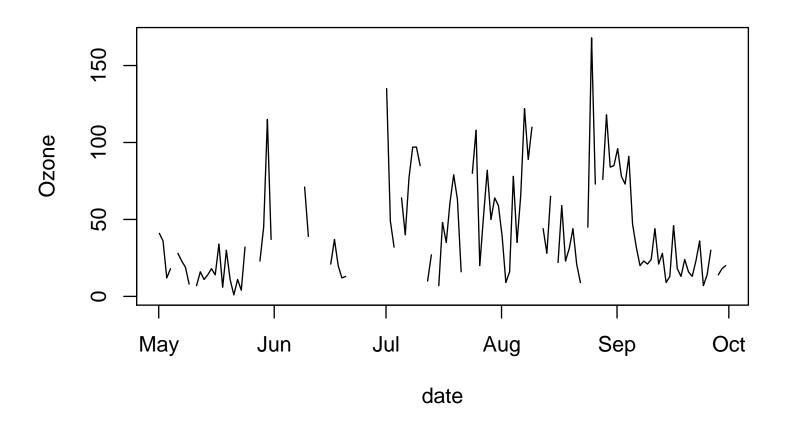

```
data(airquality)
names(airquality)
airquality$date<-with(airquality, ISOdate(1973, Month, Day))</pre>
```

All these graphs were designed at $4in \times 6in$ and stored as PDF files;

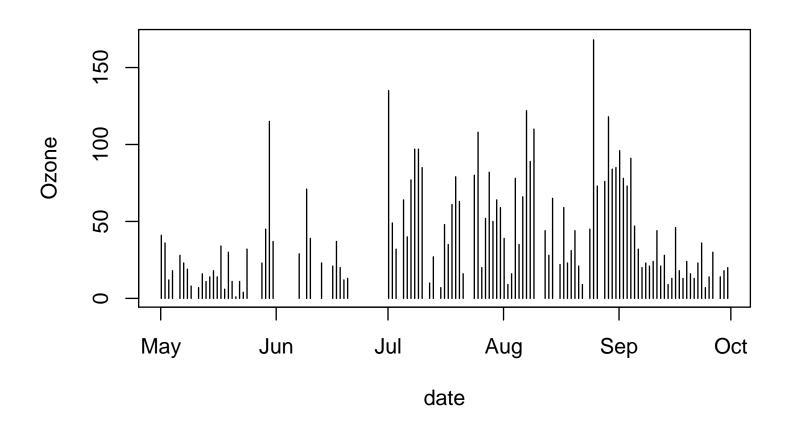

plot(Ozone~date, data=airquality)

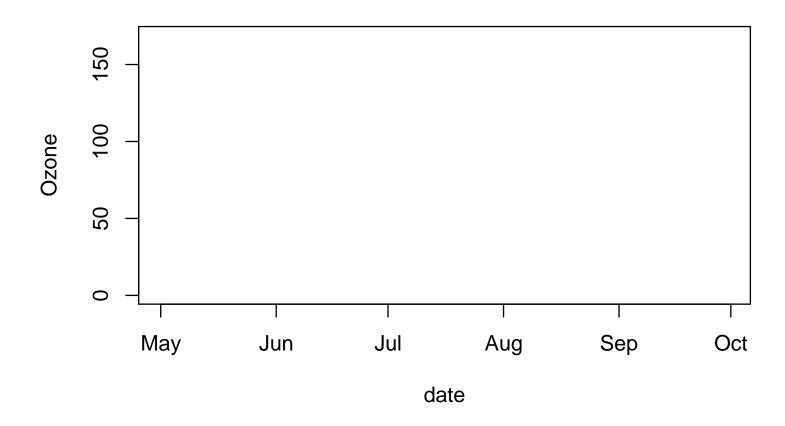

plot(Ozone~date, data=airquality,type="1")

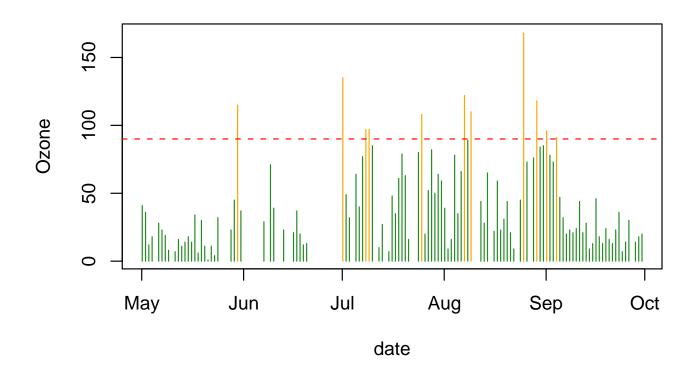

plot(Ozone~date, data=airquality,type="h")

plot(Ozone~date, data=airquality,type="n")

Commands to do a more complex plot; bad <- ifelse(airquality\$0zone>=90, "orange", "forestgreen") plot(Ozone~date, data=airquality, type="h", col=bad) abline(h=90, lty=2, col="red")

Notes

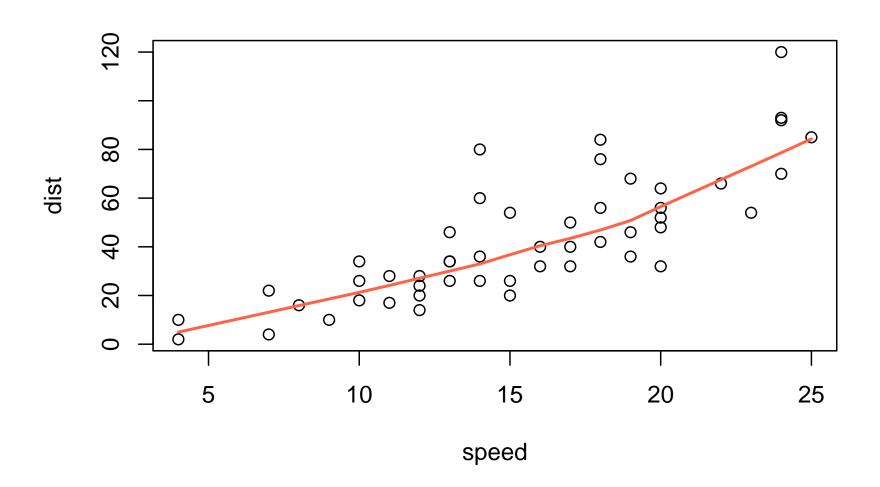

- type= controls how data are plotted. type="n" is not as useless as it looks: it can set up a plot for latter additions.
- Colors can be specified by name (the colors() function gives all the names), by red/green/blue values ("#rrggbb" with six base-sixteen digits) or by position (1:8) in the standard palette of 8 colors.
- abline draws a single straight line on a plot
- ifelse() selects between two vectors based on a logical variable.
- 1ty specifies the line type: 1 is solid, 2 is dashed, 3 is dotted, then it gets more complicated. See ?par, then search for 1ty

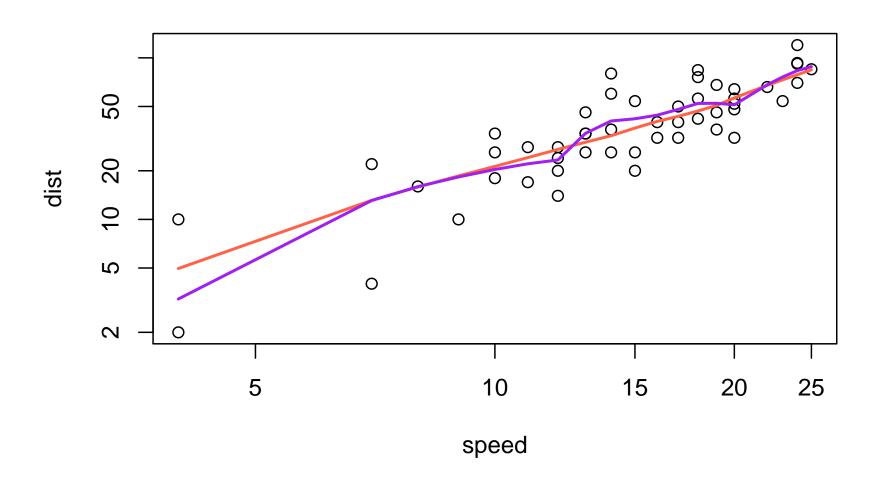

More example commands

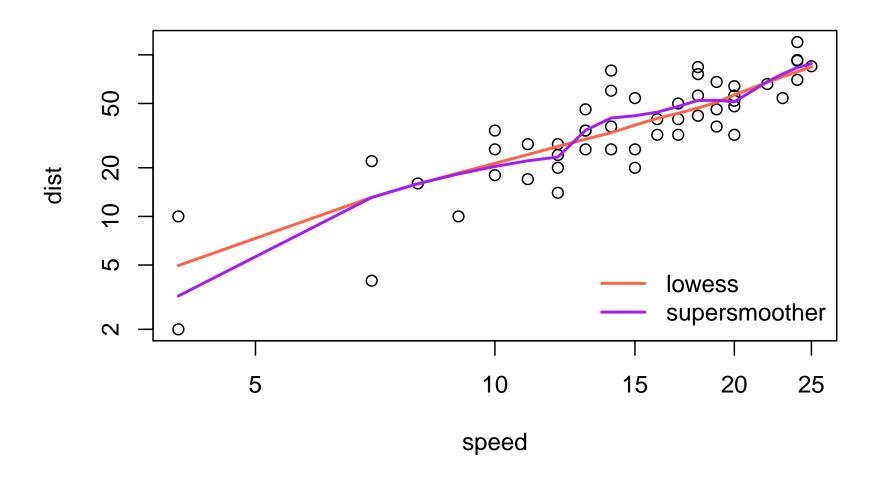

```
data(cars)
plot(dist~speed,data=cars)
with(cars, lines(lowess(speed, dist), col="tomato", lwd=2))

plot(dist~speed,data=cars, log="xy")
with(cars, lines(lowess(speed, dist), col="tomato", lwd=2))
with(cars, lines(supsmu(speed, dist), col="purple", lwd=2))

legend("bottomright", legend=c("lowess","supersmoother"),bty="n", lwd=2, col=c("tomato","purple"))
```

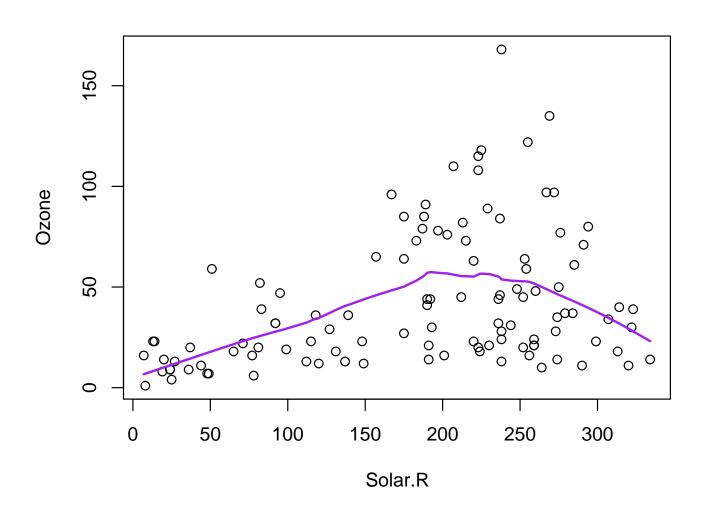

Notes

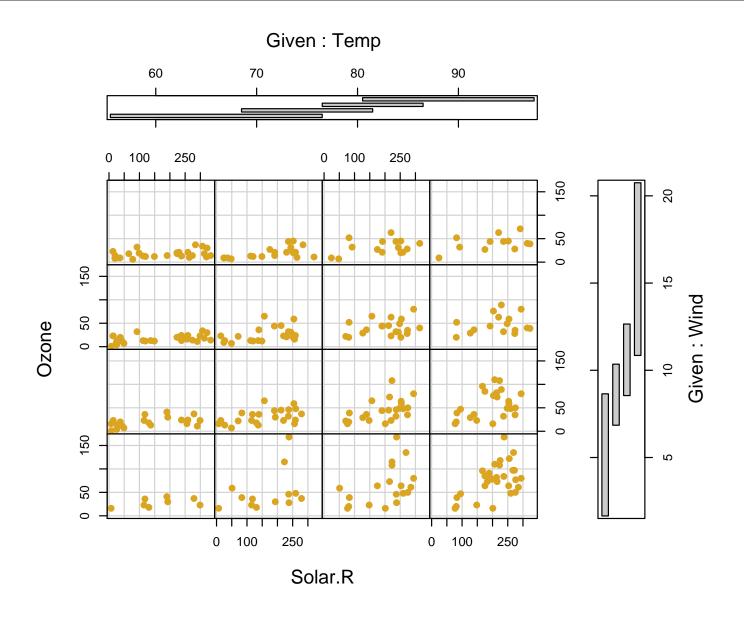

- lines() adds lines to an existing plot (and points() adds points)
- lowess() and supsmu() are scatterplot smoothers. They calculate smooth curves that fit the relationship between y and x locally. Their output has attributes x and y, that generic function lines() can cope with
- log="xy" asks for both axes to be logarithm (log="x" would just be the x-axis)
- legend() adds a legend

Ozone is a secondary pollutant, it is produced from organic compounds and atmostpheric oxygen in reactions catalyzed by nitrogen oxides and powered by su nlight.

However, looking at ozone concentrations in NY in summer we see a non-monotone relationship with sunlight

Here we draw a scatterplot of Ozone vs Solar.R for various subranges of Temp and Wind. For more examples like this, see the commands in the lattice package.

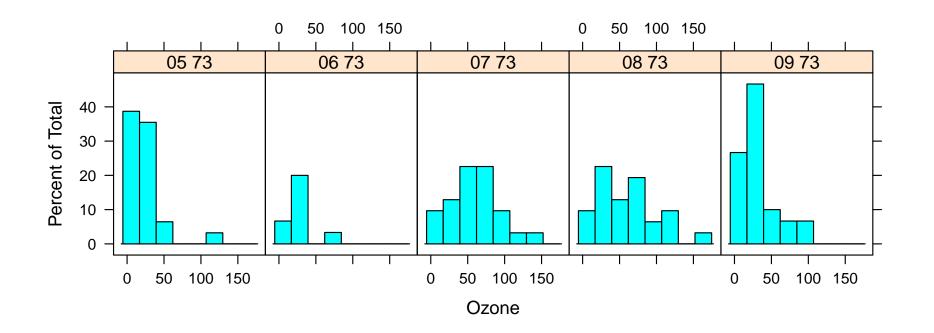

- A 4-D relationship is illustrated; the Ozone/sunlight relationship changes in strength depending on both the Temperature and Wind
- The vertical bar | is statistician-speak for 'conditioning on' (nb this is different to use of |'s meaning as Boolean 'OR')
- The horizontal/vertical 'shingles' tell you which data appear in which plot. The overlap can be set to zero, if preferred
- coplot()'s default layout is a bit odd; try setting rows, columns to different values
- For more plotting commands that support conditioning, see library(help="lattice")

Conditioning plots: general

Functions in the lattice package allow various forms of conditioning plot — here for histograms;

```
library("lattice")
airquality$date <- with(airquality, ISOdate(1973,Month,Day))
airquality$month <- strftime(airquality$date, "%m %y")
histogram(~Ozone|month, data=airquality)</pre>
```

Conditioning plots: general

Some other plots that can be conditioned;

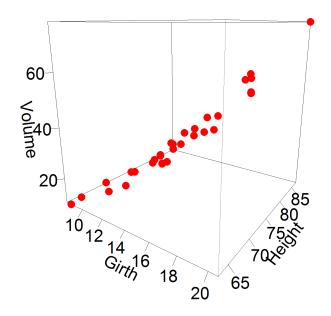

- xyplot() for scatterplots more flexible version of coplot()
- barchart() for boxplots
- dotplot() and stripchart()
- qq() and qqmath(), e.g. comparing to N(0,1)
- levelplot() heatmaps, see also image()
- contourplot() see also contour()
- cloud() and wireframe(), for fake 3D

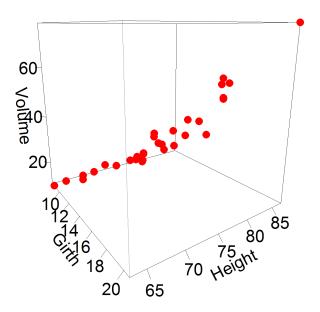

For still others see ?Lattice after loading the lattice package ... or demo(lattice).

For fine control, these functions all permit panel arguments, i.e. you can supply a function implemented in each subplot. ?panel.abline describes some pre-written versions.

persp() and friends

Should you ever need them; (and you may not!)

persp() is okay for wireframes, otherwise try cloud() first.

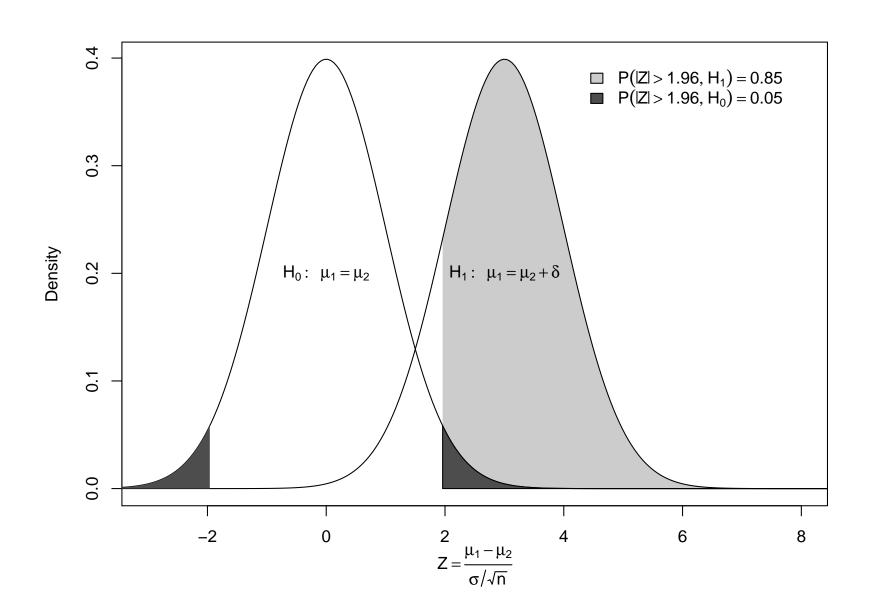

Toys: Mathematical annotation

An expression can be specified in R for any text in a graph (help(plotmath) for details). Here we annotate a figure drawn with polygon().

```
x < -seq(-10, 10, length = 400)
y1 < -dnorm(x)
y2 < -dnorm(x, m=3)
par(mar=c(5,4,2,1))
plot(x,y2,xlim=c(-3,8),type="n",
    xlab=quote(Z==frac(mu[1]-mu[2],sigma/sqrt(n))),
    vlab="Density")
polygon(c(1.96,1.96,x[240:400],10),
        c(0, dnorm(1.96, m=3), y2[240:400], 0),
        col="grey80", lty=0)
lines(x,y2)
lines(x,y1)
polygon(c(-1.96,-1.96,x[161:1],-10),
        c(0,dnorm(-1.96,m=0),y1[161:1],0),
        col="grey30",lty=0)
polygon(c(1.96,1.96,x[240:400],10),
        c(0, dnorm(1.96, m=0), y1[240:400], 0),
        col="grey30")
```
