

2022 SISG Bayesian Statistics for Genetics R Notes: Generalized Linear Models

Jon Wakefield
Departments of Statistics and Biostatistics
University of Washington

2022-07-19

Overview

In this set of notes a number of generalized linear models (GLMs) and generalized linear mixed models (GLMMs) will be fitted using Bayesian methods.

The integrated nested Laplace approximation (INLA) computational technique will be illustrated

Case control example: Data

We analyze a case control example using logistic regression models, first using likelihood methods.

The data concern the numbers of cases (of the disease Leber Hereditary Optic Neuropathy) and controls as a function of genotype at a particular location (rs6767450).

```
x <- c(0, 1, 2)
# Case data for CC CT TT
y <- c(6, 8, 75)
# Control data for CC CT TT
z <- c(10, 66, 163)
```

Case control example: Likelihood analysis

We fit the logistic regression model as a generalized linear model and then examine the estimate and an asymptotic (large sample) 95% confidence interval.

```
logitmod <- glm(cbind(y, z) ~ x, family = "binomial")
thetahat <- logitmod$coeff[2] # Log odds ratio
thetahat
##          x
## 0.4787428
exp(thetahat) # Odds ratio
##          x
## 1.614044
V <- vcov(logitmod)[2, 2] # standard error^2
# Asymptotic confidence interval for odds ratio
exp(thetahat - 1.96 * sqrt(V))
```

```

##      x
## 0.9879159
exp(thetahat + 1.96 * sqrt(V))
##      x
## 2.637004

```

Now let's look at a likelihood ratio test of $H_0 : \theta = 0$ where θ is the log odds ratio associated with the genotype (multiplicative model).

```

logitmod
##
## Call: glm(formula = cbind(y, z) ~ x, family = "binomial")
##
## Coefficients:
## (Intercept)          x
## -1.8077        0.4787
##
## Degrees of Freedom: 2 Total (i.e. Null);  1 Residual
## Null Deviance:      15.01
## Residual Deviance: 10.99    AIC: 27.79
dev <- logitmod>null.deviance - logitmod$deviance
dev
## [1] 4.01874
pchisq(dev, df = logitmod$df.residual, lower.tail = F)
## [1] 0.04499731

```

So just significant at the 5% level.

FTO Example: Data

We reproduce the least squares analysis of the FTO data.

The `lm` function uses MLE, which is equivalent to ordinary least squares.

```

load(url("http://faculty.washington.edu/kenrice/sisgbayes/yX_FTO.Rdata"))
liny <- yX$y
linxg <- yX$X[, "xg"]
linxa <- yX$X[, "xa"]
linxint <- yX$X[, "xg"] * yX$X[, "xa"]
ftodf <- list(liny = liny, linxg = linxg, linxa = linxa,
               linxint = linxint)

```

FTO Example: LS fit

```

ols.fit <- lm(liny ~ linxg + linxa + linxint, data = ftodf)
summary(ols.fit)
##
## Call:
## lm(formula = liny ~ linxg + linxa + linxint, data = ftodf)
## 
## Residuals:

```

```

##      Min     1Q Median     3Q    Max
## -4.8008 -0.8844  0.2993  1.2270  2.4819
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)
## (Intercept) -0.06822   1.42230 -0.048  0.9623
## linxg        2.94485   2.01143  1.464  0.1625
## linxa        2.84421   0.42884  6.632 5.76e-06 ***
## linxint      1.72948   0.60647  2.852  0.0115 *
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 1.918 on 16 degrees of freedom
## Multiple R-squared:  0.9393, Adjusted R-squared:  0.9279
## F-statistic: 82.55 on 3 and 16 DF,  p-value: 5.972e-10

```

INLA

Integrated nested Laplace approximation (INLA) is a technique for carrying out Bayesian computation. It is not a standard R package and must be downloaded from the development website. The `inla` function is the work horse.

```

# install.packages('INLA',
# repos='http://www.math.ntnu.no/inla/R/stable')
library(INLA)
# Data should be input to INLA as either a list
# or a dataframe
formula <- liny ~ linxg + linxa + linxint
lin.mod <- inla(formula, data = ftodf, family = "gaussian")

```

We might wonder, where are the priors?

We didn't specify any... but INLA has default choices.

FTO example via INLA: Lots of output available!

```

```

The posterior means and standard deviations are in very close agreement with the OLS fits presented earlier.

FTO Posterior marginals

We now examine the posterior marginal distributions.

The posterior marginal distribution for the vector of regression coefficients (including the intercept) is given below, and then we examine the posterior marginal on the precision, $1/\sigma_\epsilon$.

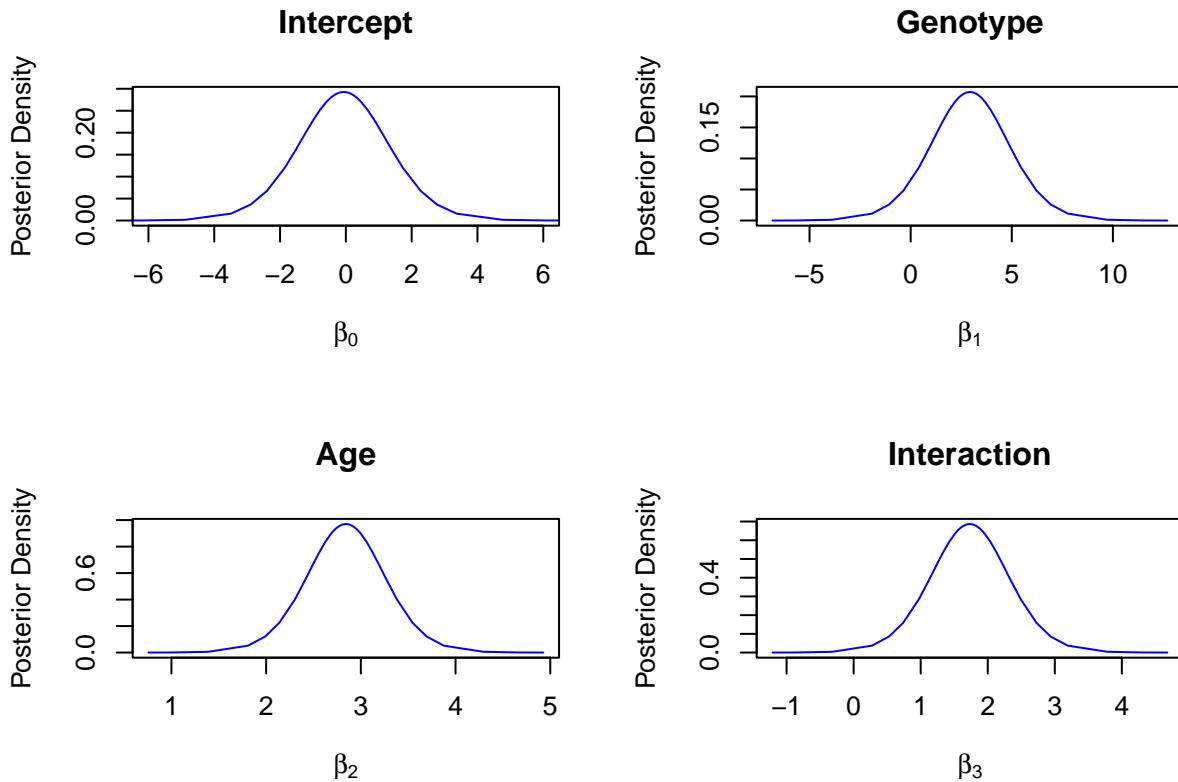

Check out the files that are written.

```

par(mfrow = c(2, 2))
plot(lin.mod$marginals.fixed$(Intercept)[, 2] ~ lin.mod$marginals.fixed$(Intercept)[,
  1], xlab = expression(beta[0]), ylab = "Posterior Density",
  type = "l", col = "blue", xlim = c(-6, 6), main = "Intercept")
plot(lin.mod$marginals.fixed$linxg[, 2] ~ lin.mod$marginals.fixed$linxg[, 1],
  xlab = expression(beta[1]), ylab = "Posterior Density",
  type = "l", col = "blue", main = "Genotype")
plot(lin.mod$marginals.fixed$linxa[, 2] ~ lin.mod$marginals.fixed$linxa[, 1],
  xlab = expression(beta[2]), ylab = "Posterior Density",
  type = "l", col = "blue", main = "Age")
plot(lin.mod$marginals.fixed$linxint[, 2] ~ lin.mod$marginals.fixed$linxint[, 1],
  xlab = expression(beta[3]), ylab = "Posterior Density",
  type = "l", col = "blue", main = "Age")

```

```
1], xlab = expression(beta[3]), ylab = "Posterior Density",
type = "l", col = "blue", main = "Interaction")
```

FTO example via INLA

In order to carry out model checking we rerun the analysis, but now switch on a flag to obtain fitted values.

```
lin.mod <- inla(liny ~ linxg + linxa + linxint, data = ftodf,
  family = "gaussian", control.predictor = list(compute = TRUE))
fitted <- lin.mod$summary.fitted.values[, 1]
# Now extract the posterior median of the
# measurement error sd
sigmamed <- 1/sqrt(lin.mod$summary.hyperpar[, 4])
```

FTO: Residual analysis

With the fitted values we can examine the fit of the model. In particular:

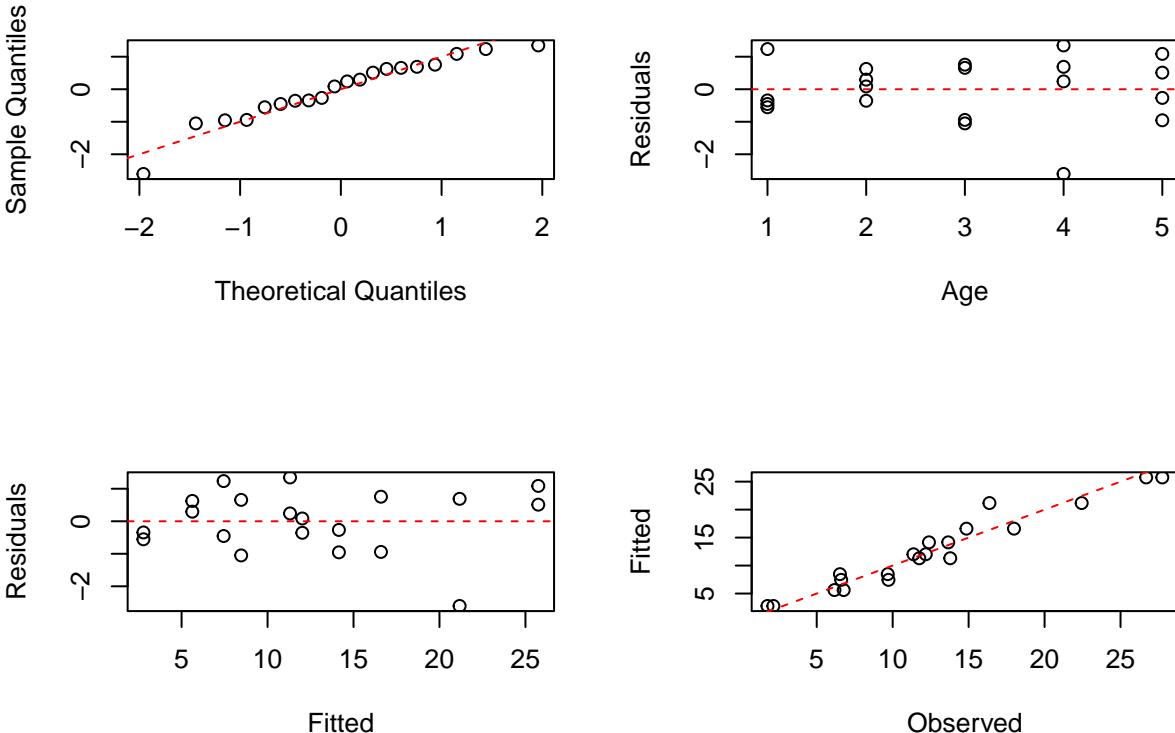

- Normality of the errors (sample size is relatively small).
- Errors have constant variance (and are uncorrelated).

The code below forms residuals and then forms

- a QQ plot to assess normality,
- a plot of residuals versus age, to assess linearity,
- a plot of residuals versus fitted values, to see if an unmodeled mean-variance relationship) and
- a plot of fitted versus observed for an overall assessment of fit.

```
residuals <- (liny - fitted)/sigmamed
par(mfrow = c(2, 2))
qnorm(residuals, main = "")
abline(0, 1, lty = 2, col = "red")
plot(residuals ~ linxa, ylab = "Residuals", xlab = "Age")
abline(h = 0, lty = 2, col = "red")
plot(residuals ~ fitted, ylab = "Residuals", xlab = "Fitted")
abline(h = 0, lty = 2, col = "red")
plot(fitted ~ liny, xlab = "Observed", ylab = "Fitted")
abline(0, 1, lty = 2, col = "red")
```

The model assumptions do not appear to be greatly invalidated here.

Case-Control Example: INLA Analysis

We perform two analyses.

The first analysis uses the default priors in INLA (which are relatively flat).

```
x <- c(0, 1, 2)
y <- c(6, 8, 75)
z <- c(10, 66, 163)
cc.dat <- as.data.frame(rbind(y, z, x))
cc.mod <- inla(y ~ x, family = "binomial", data = cc.dat,
  Ntrials = y + z)
```

```

summary(cc.mod)
##

```

Prior choice

Suppose that for the odds ratio e^β we believe there is a 50% chance that the odds ratio is less than 1 and a 95% chance that it is less than 5; with $q_1 = 0.5$, $\theta_1 = 1.0$ and $q_2 = 0.95$, $\theta_2 = 5.0$, we obtain lognormal parameters $\mu = 0$ and $\sigma = (\log 5)/1.645 = 0.98$.

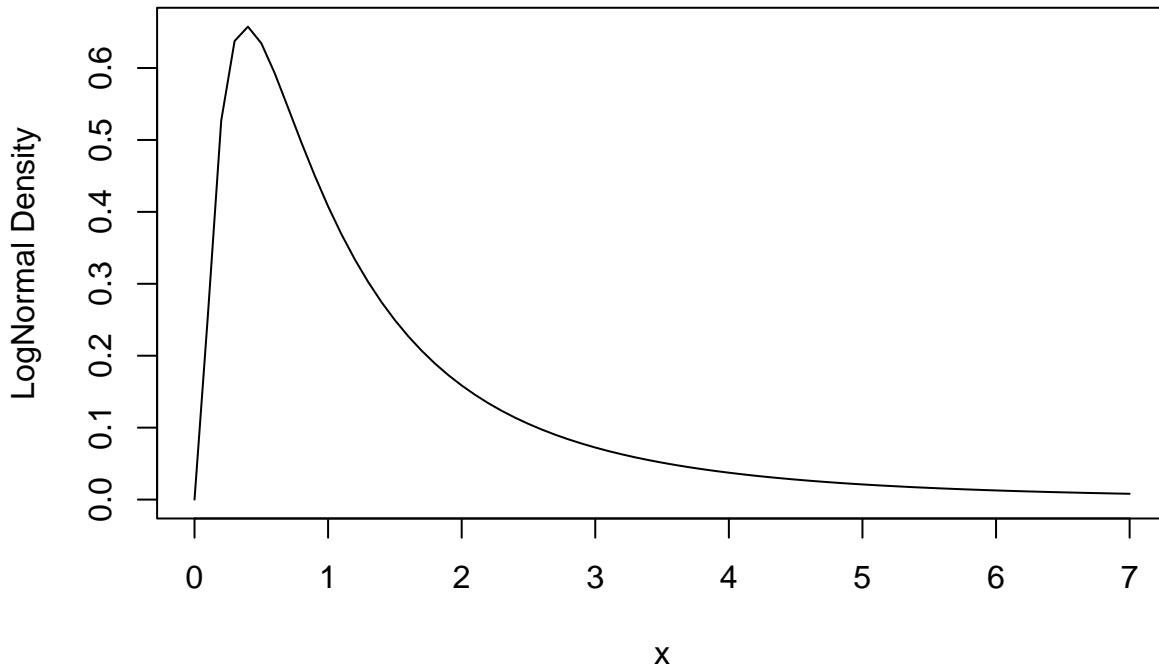

There is a function in the **SpatialEpi** package to find the parameters, as we illustrate.

```

library(SpatialEpi)
lnprior <- LogNormalPriorCh(1, 5, 0.5, 0.95)
lnprior
## $mu
## [1] 0
##
## $sigma
## [1] 0.9784688

plot(seq(0, 7, 0.1), dlnorm(seq(0, 7, 0.1), meanlog = lnprior$mu,
  sdlog = lnprior$sigma), type = "l", xlab = "x",
  ylab = "LogNormal Density")

```

```

# Now with informative priors
W <- LogNormalPriorCh(1, 1.5, 0.5, 0.975)$sigma^2
cc.mod2 <- inla(y ~ x, family = "binomial", data = cc.dat,
                  Ntrials = y + z, control.fixed = list(mean.intercept = c(0),
                  prec.intercept = c(0.1), mean = c(0), prec = c(1/W)))
summary(cc.mod2)

```

The quantiles for θ can be translated to odds ratios by exponentiating.

Longitudinal Example

We follow Wang et al.(2018, Section 5.3) and analyze longitudinal data on reading scores (PIAT = Peabody Individual Achievement Test) measured on $n = 89$ children at ages 6.5, 8.5 and 10.5 years.

We expect scores on the same children to be correlated, and one way of acknowledging this is to include a random intercept in the model.

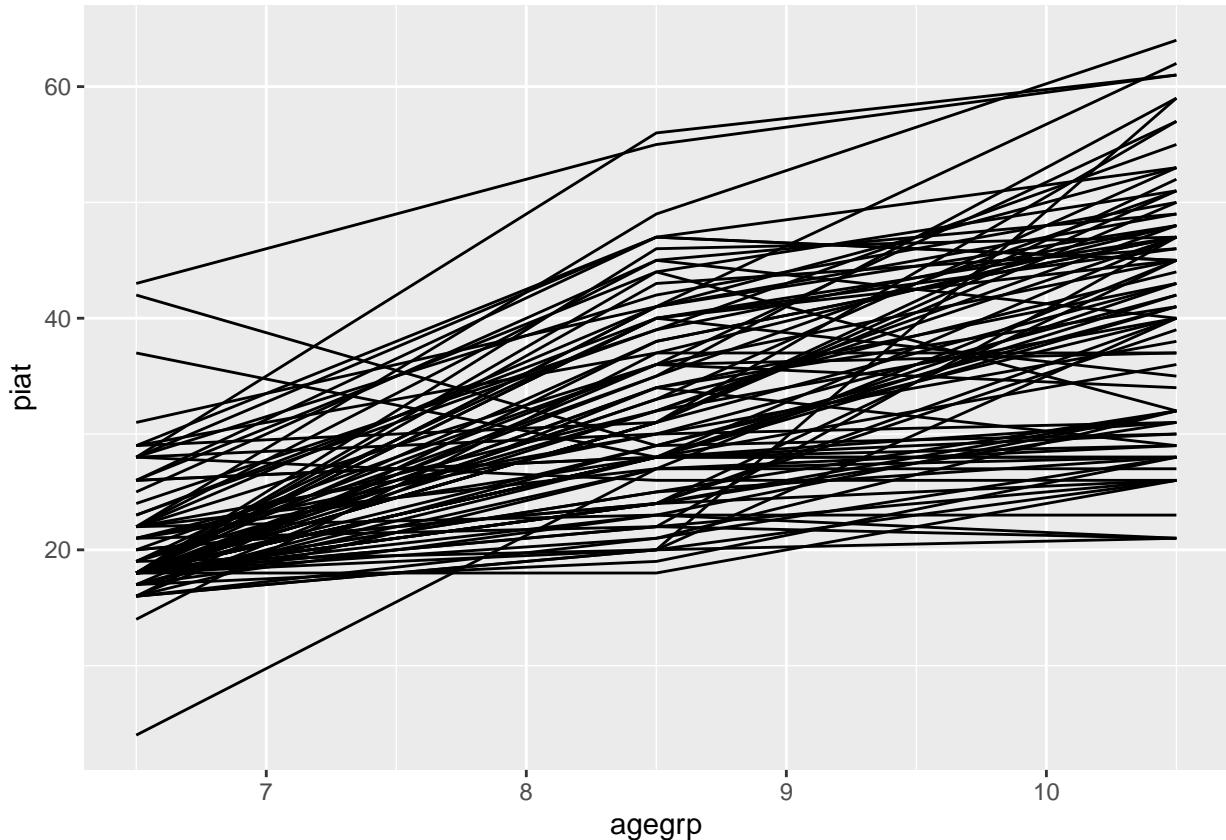

We let y_{ij} represent the reading score of child i at age t_j , with $t_1 = 6.5$, $t_2 = 8.5$ and $t_3 = 10.5$.

```

library(ggplot2)
library(brinla)
data(reading, package = "brinla")

ggplot(reading, aes(agegrp, piat, group = id)) + geom_line()

```

A linear mixed effects model (LMM)

We see a clear improvement in scores, which looks linear, but obvious between-child variartion.

We fit the model

$$\begin{aligned} Y_{ij} &= \beta_0 + \alpha_i + \beta_1 t_j + \epsilon_{ij} \\ \alpha_i &\sim_{iid} N(0, \sigma_\alpha^2) \\ \epsilon_{ij} &\sim_{iid} N(0, \sigma_\epsilon^2) \end{aligned}$$

where β_0, β_1 are fixed effects, α_i is a child-specific random effect and ϵ_{ij} is measurement error.

LMM: Frequentist Analysis

We center age to provide an easier interpretation of the intercept, and (later) it will be easier to specify priors.

```
library(lme4)
reading$cagegrp <- reading$agegrp - 8.5
lmod <- lmer(piat ~ cagegrp + (1 | id), reading)
fixef(lmod)
## (Intercept)      cagegrp

Bayesian Analysis

For the Bayesian analysis we have priors on the fixed effects: $\beta_0 \sim N(40, 10^2)$, $\beta_1 \sim N(0, 4^2)$.

For the measurement error, the default relatively uninformative prior usually suffices (there is a lot of information in the data on the measurement error).

For the random effects variance we use a penalized complexity (PC) prior (Simpson et al.-2017) in which we say that $\Pr(\sigma_\alpha > 10) = 0.05$.

```
prior.fixed <- list(mean.intercept = 40, prec.intercept = 1/10^2,
  mean = 0, prec = 1/4^2)
pcprior <- list(prec = list(prior = "pc.prec", param = c(10,
  0.05)))
formula <- piat ~ cagegrp + f(id, model = "iid", hyper = pcprior)
imod <- inla(formula, family = "gaussian", data = reading,
  control.fixed = prior.fixed)
imod$summary.fixed[, 1:5]
##               mean      sd 0.025quant 0.5quant 0.975quant
## (Intercept) 31.268579 0.7069854 29.880348 31.268108 32.659491
## cagegrp     5.011015 0.2514784  4.516968  5.011122  5.504452
bri.hyperpar.summary(imod)
##                   mean      sd   q0.025   q0.5   q0.975

## SD for id                      5.402545 0.6279812 4.257375 5.372211 6.720557
##                   mode
## SD for the Gaussian observations 6.660440
## SD for id                      5.323538
bri.hyperpar.plot(imod)
```

Prediction

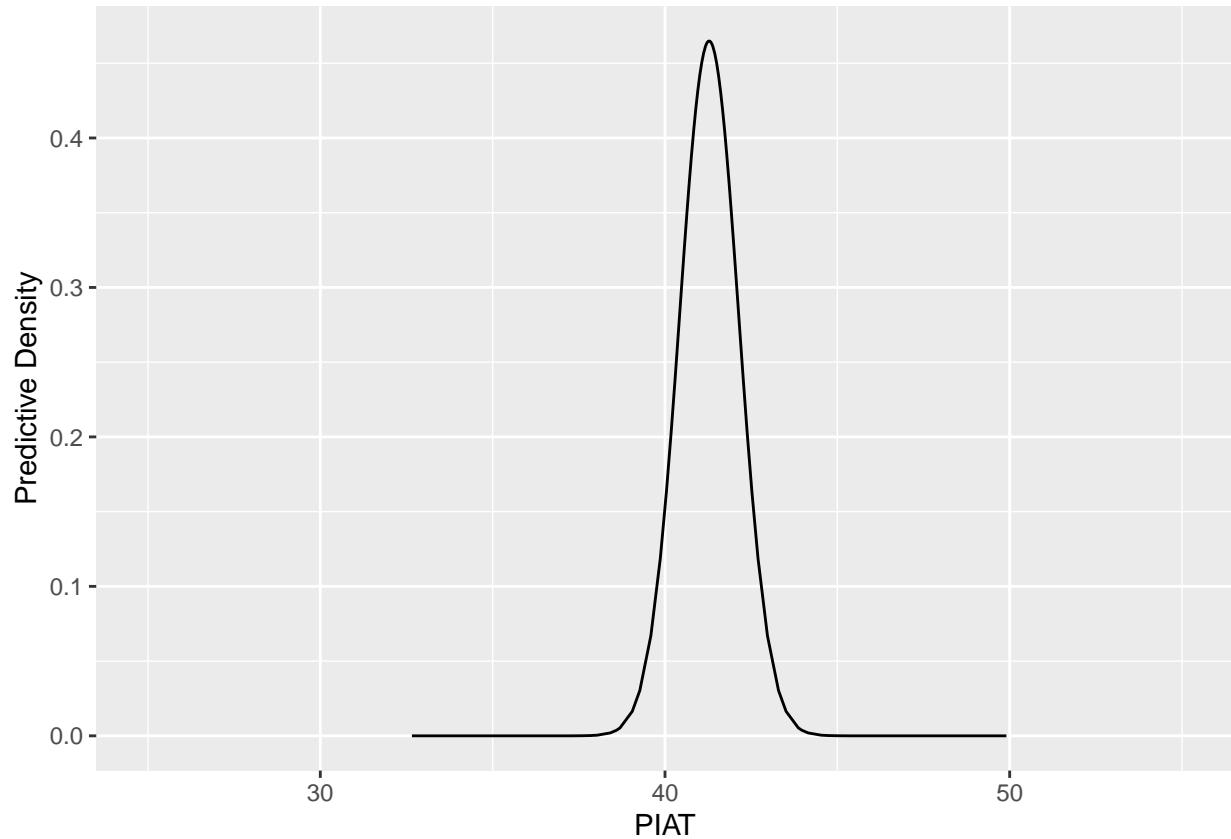

We now suppose we have a new child with measurements of 18 and 25 at years 6.5 and 8.5, and we want to predict their outcome at 10.5, under the assumption that they are exchangeable with the individuals in the dataset.

We code the missing value as NA and add the individual to the dataset.

Then we obtain the fitted value for this point (which is the 270th in the dataset).

```
newsub <- data.frame(id=90, agegrp = c(6.5,8.5,10.5), cagegrp = c(-2,0,2),
                      piat=c(20, 31, NA))
nreading <- rbind(reading, newsub)
prior.fixed <- list(mean.intercept = 40, prec.intercept = 1 / 10^2,
                     mean = 0, prec = 1 / 4^2)
pcprior <- list(prec = list(prior="pc.prec",
                            param = c(10,0.05)))
formula <- piat ~ cagegrp + f(id, model="iid", hyper = pcprior)
imodp <- inla(formula, family="gaussian", data=nreading,
               control.fixed = prior.fixed, control.predictor=list(compute=TRUE))
pm90 <- imodp$marginals.fitted.values[[270]]

dens_plot <- ggplot(data.frame(pm90),aes(x,y))+geom_line()+xlim(c(25,55))+
  xlab("PIAT") + ylab("Predictive Density")
print(dens_plot)
```

Approximate Bayes

We return to the case control example seen earlier.

Below we construct the posterior by hand

```
x <- c(0,1,2)
y <- c(6,8,75)
z <- c(10,66,163)
logitmod <- glm(cbind(y,z)~x,family="binomial")
thetahat <- logitmod$coef[2]
V <- vcov(logitmod)[2,2]
# 97.5 point of prior is log(1.5) so that we with prob
# 0.95 we think theta lies in (2/3,1.5)
#
W <- LogNormalPriorCh(1,1.5,0.5,0.975)$sigma^2
```

Approximate Bayes: estimation

```
r <- W/(V + W)
r
## [1] 0.4055539
# Not so much data here, so weight on prior is
```

```

# high. Bayesian posterior median
exp(r * thetahat)
##      x
## 1.214286
# Shrunk towards prior median of 1 Note: INLA
# estimate (with same prior) is 1.22 and
# approximate posterior SD here is
# sqrt(rV)=0.159, INLA version is 0.154.
# Bayesian approximate 95% credible interval
exp(r * thetahat - 1.96 * sqrt(r * V))
##      x
## 0.8882832
exp(r * thetahat + 1.96 * sqrt(r * V))
##      x
## 1.659932

```

Approximate Bayes: hypothesis testing

Now we turn to testing using Bayes factors.

We examine the sensitivity to the prior on the alternative, π_1 .

```

pi1 <- c(1/2, 1/100, 1/1000, 1/10000, 1/1e+05) # 5 prior probs on the null
source("http://faculty.washington.edu/jonno/BFDP.R")
BFcall <- BFDPfunV(theta, V, W, pi1)
BFcall
## $BF
##      x
## 0.6182773
##
## $pH0
##      x
## 0.256323
##
## $pH1
##      x
## 0.4145761
##
## $BFDP
## [1] 0.3820589 0.9839253 0.9983836 0.9998383 0.9999838

```

So data are twice as likely under the alternative (0.502) as compared to the null (0.256).

Apart from under the 0.5 prior, under these priors the overall evidence is of no association.

Exercises

- For the case-control data, suppose we wish to specify a prior with a 5% point for the odds ratio of 0.2 and a 95% point for the odds ratio of 5:
 - Use the `LogNormalPriorCh` to find the appropriate normal distribution for the log odds ratio
 - Use this prior within INLA and report the posterior median and a 95% interval for the log odds ratio

- Are these summaries very different from the INLA fit with default priors?
