AMath 483/583 — Lecture 15 — April 29, 2011	Notes:
Todov	
Today:	
OpenMP     Fine grain ve seeree grain perclusion	
Fine grain vs. coarse grain parallelism	
Next week:	
Iterative methods for linear systems	
Adaptive quadrature	
Start MPI	
Read: Class notes and references	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Dependencies in loops	Notes:
do i=1,n	
z(i) = x(i) + y(i)	
$w(i) = \cos(z(i))$	
enddo	
There is a data dependence between the two statements in this	
loop.	
The value $w(i)$ cannot be computed before $z(i)$ .	
However, this could be paralellized with a parallel do since the	
same thread will always execute both statements in the right	
order for each <i>i</i> .	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Matrix-matrix multiplication	Notes:
<pre>!\$omp parallel do private(i,k)</pre>	
do j=1,n	
do i=1, n	
c(i,j) = 0.d0	
do k=1, n	
$c(i,j) = c(i,j) + a(i,k) \star b(k,j)$ enddo	
enddo enddo	
enddo	
This works since a (4, 1) is any modified by thread herdling	
This works since $c(i, j)$ is only modified by thread handling column j.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

# Thread-safe functions

### Consider this code:

```
!$omp parallel do
do i=1,n
    y(i) = myfcn(x(i))
    enddo
```

Does this give the same results as the serial version?

Maybe not... it depends on what the function does!

If this gives the same results regards of the order threads call for different values of i, then the function is thread safe.

R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

# Thread-safe functions

## A thread-safe function:

```
function myfcn(x)
    real(kind=8), intent(in) :: x
    real(kind=8), intent(out) :: myfcn
    real(kind=8) :: z ! local variable
    z = exp(x)
    myfcn = z*cos(x)
end function myfcn
```

Executing this function for one value of  ${\rm x}$  is completely independent of execution for other values of  ${\rm x}.$ 

Note that each call creates a new local value z on the call stack, so z is private to the thread executing the function.

R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

# Non-Thread-safe functions

Suppose z, count are global variables defined in module globals.f90.

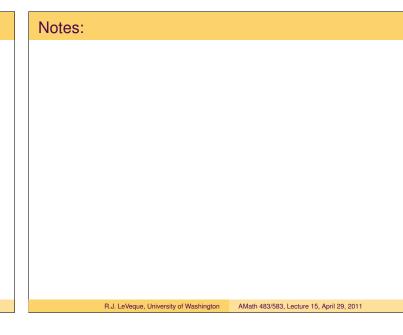

# Then this function is not thread-safe:

```
function myfcn(x)
    real(kind=8), intent(in) :: x
    real(kind=8), intent(out) :: myfcn
    use globals
    count = count+1 ! counts times called
    z = exp(x)
    myfcn = z*cos(x) + count
end function myfcn
```

The value of count seen when calling y(i) = myfcn(x(i)) will depend on the order of execution of different values of i.

Moreover, z might be modified by another thread between when it is computed and when it is used.

# Notes: R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

Aside on global variables in Fortran       Notes:         module globals       implicit none         save       integer :: count         integer :: count       real(kind=8) :: z	
<pre>implicit none save integer :: count real(kind=8) :: z</pre>	
<pre>end module globals The save command says that values of these variables should be saved from one use to the next. Fortran 77 and before: Instead used common blocks:     common /globals/ z, count can be included in any file where z and count should be</pre>	
available. (Also not thread safe!)	2011
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2	:011
Non-Thread-safe functions Notes:	
Beware of input or output	
Suppose unit 20 has been opened for reading in the main program, value on line $i$ should be used in calculating $y(i)$	
This function is not thread-safe:	
<pre>function myfcn(x)     real(kind=8), intent(in) :: x     real(kind=8), intent(out) :: myfcn     real(kind=8) :: z      read(20,*) z     myfcn = z*cos(x) </pre>	
end function myfcn Will work in serial mode but if threads execute in different order,	
will give wrong results.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2	2011
Pure subroutines and functions Notes:	
<pre>A subroutine can be declared pure if it: • Does not alter global variables, • Does not do I/O, • Does not declare local variables with the save attribute, such as real, save :: z • For functions, does not alter any input arguments. Example: pure subroutine f(x,y) implicit none real(kind=8), intent(in) :: x real(kind=8), intent(inout) :: y y = x**2 + y end subroutine f</pre>	
Good idea even for sequential codes: Allows some compiler optimizations.	

# Forall statement

# In place of

```
do i=1,n
x(i) = 2.d0*i
end do
```

# can write

```
forall (i=1:n)
    x(i) = 2.d0*i
end forall
```

Tells compiler that the statements can execute in any order.

Also may lead to compiler optimization even on serial computer.

R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

# Forall statement

### Nested loops can be written with forall:

### Can include masks:

R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

# OpenMP — beyond parallel loops

The directive !Somp parallel is used to create a number of threads that will each execute the same code...

```
!$omp parallel
   ! some code
!$omp end parallel
```

The code will be executed nthreads times.

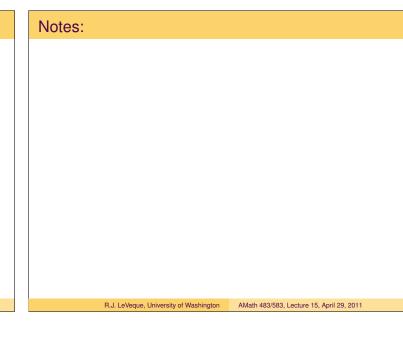

SPMD: Single program, multiple data

### Terminology note:

SIMD: Single instruction, multiple data

refers to hardware (vector machines) that apply same arithmetic operation to a vector of values in lock-step. SPMD is a software term — need not be in lock step.

# OpenMP parallel with do loops Notes: Note: This code ... !\$omp parallel do i=1,10 print \*, "i = ",i enddo !\$omp end parallel The entire do loop (i=1,2,...,10) will be executed by each thread! With 2 threads, 20 lines will be printed. ... is not the same as: !\$omp parallel do do i=1,10 print \*, "i = ",i enddo !\$omp end parallel do R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 OpenMP parallel with do loops Notes: !\$omp parallel do do i=1,10 print \*, "i = ",i enddo !\$omp end parallel do is shorthand for: !\$omp parallel !\$omp do do i=1,10 print \*, "i = ",i enddo !\$omp end do !\$omp end parallel More generally, if ! somp do is inside a parallel block, then the loop is split between threads rather than done in total by each R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011 OpenMP parallel with do loops Notes: The ! \$omp do directive is useful for ... !\$omp parallel ! some code executed by every thread !\$omp do do i=1,n ! loop to be split between threads enddo !\$omp end do ! more code executed by every thread !\$omp end parallel

Some other useful directives Notes:	
Execution of part of code by a single thread:	
!\$omp parallel ! some code executed by every thread	
!\$omp single ! code executed by only one thread !\$omp end single	
!\$omp end parallel	
Can also use <code>!somp master</code> to force execution by master thread.	
Example: Initializing or printing out a shared variable.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Some other useful directives Notes:	
barriers:	
!\$omp parallel ! some code executed by every thread	
!\$omp barrier	
! some code executed by every thread !\$omp end parallel	
Every thread will stop at barrier until all threads have reached this point.	
Make sure all threads reach barrier or code will hang!	
R.J. LeVegue, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Some other useful directives Notes:	
Sections:	
!\$omp parallel	
!\$omp sections	
!\$omp section ! code executed by only one thread	
!\$omp section ! code executed by a different thread	
!\$omp end sections	
!\$omp end parallel	
Example: Read in two large data files simultaneously.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

Fine vs. coarse grain parallelism	Notes:
Fine grain: Parallelize at the level of individual loops, splitting work for each loop between threads.	
Coarse grain: Split problem up into large pieces and have each thread deal with one piece.	
May need to synchronize or share information at some points.	
Domain Decomposition: Splitting up a problem on a large domain (e.g. three-dimensional grid) into pieces that are handled separated (with suitable coupling).	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Solution of independent ODEs by Euler's method	Notes:
Solve $u'_i(t) = c_i u_i(t)$ for $t \ge 0$ with initial condition $u_i(0) = \eta_i$ .	
Exact solution: $u_i(t) = e^{c_i t} \eta_i$ .	
Euler method: $u_i(t + \Delta t) \approx u_i(t) + \Delta t c_i u_i(t) = (1 + c_i \Delta t) u_i(t).$	
Implement this for large number of time steps for $i = 1, 2,, n$ with $n$ large too.	
This problem is embarassingly parallel: Problem for each $i$ is completely decoupled from problem for any other $i$ . Could solve them all simultaneously with no communication needed.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	D L Jakawa Ukawata (Washington Alluh (2017) Jakwa (5, Avil 20, 2014
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011
Fine grain solution with parallel do loops	Notes:
<pre>!\$omp parallel do do i=1,n     u(i) = eta(i)</pre>	
enddo	
do m=1,nsteps !\$omp parallel do	
do i=1,n u(i) = (1.d0 + dt*c(i))*u(i)	
u(1) = (1.d0 + dt*C(1))*u(1) enddo enddo	
Note that threads are forked nsteps+1 times.	
Requires shared memory: don't know which thread will handle each i.	
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011	R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011

oarse grain solution of ODEs	Notes:		
Split up $i = 1, 2,, n$ into nthreads disjoint sets.			
A set goes from i=istart to i=iend			
These private values are different for each thread.			
Each thread handles 1 set for the entire problem.			
<pre>!\$omp parallel private(istart,iend,i,m) istart = ??</pre>			
iend = ??			
<pre>do i=istart,iend u(i) = eta(i) enddo</pre>			
<pre>do m=1,nsteps     do i=istart,iend         u(i) = (1.d0 + dt*c(i))*u(i)         enddo</pre>			
enddo !\$omp end parallel			
Threads are forked only once,			
Each thread only needs subset of data. R.J. LeVegue, University of Washington AMath 483/583, Lecture 15, April 29, 2011		R.J. LeVeque, University of Washington	AMath 483/583, Lecture 15, April 29, 2011
etting istart and iend	Notes:		
Example: If n=100 and nthreads = 2, we would want:			
Thread 0: istart= 1 and iend= 50,			
Thread 1: istart=51 and iend=100.			
If nthreads divides n evenly			
<pre>points_per_thread = n / nthreads</pre>			
<pre>!\$omp parallel private(thread_num, istart, iend, i) thread_num = 0 ! needed in serial mode</pre>			
!\$ thread_num = omp_get_thread_num()			
istart = thread_num * points_per_thread + 1 iend = (thread_num+1) * points_per_thread			
do i=istart,iend ! work on thread's part of array enddo			
 !\$omp end parallel			
R.J. LeVeque, University of Washington AMath 483/583, Lecture 15, April 29, 2011		R.J. LeVeque, University of Washington	AMath 483/583, Lecture 15, April 29, 2011
etting istart and iend more generally	Notes:		
Example: If n=101 and nthreads = 2, we would want:			
Thread 0: istart= 1 and iend= 51,			
Thread 0: istart= 1 and iend= 51, Thread 1: istart=52 and iend=101.			
Thread 0: istart= 1 and iend= 51, Thread 1: istart=52 and iend=101. If nthreads might not divide n evenly			
<pre>Thread 0: istart= 1 and iend= 51, Thread 1: istart=52 and iend=101. If nthreads might not divide n evenly points_per_thread = (n + nthreads - 1) / nthreads</pre>			
Thread 0: istart= 1 and iend= 51, Thread 1: istart=52 and iend=101. If nthreads might not divide n evenly			

istart = thread\_num \* points\_per\_thread + 1
iend = min((thread\_num+1) \* points\_per\_thread, n) do i=istart,iend ! work on thread's part of array enddo

!\$omp end parallel
