

TCSS 558: APPLIED DISTRIBUTED COMPUTING

Chapter 6 – Coordination – IV Final Exam Practice

Wes J. Lloyd
School of Engineering
& Technology (SET)
University of Washington - Tacoma

The diagram illustrates several network topologies: Star (a central node connected to multiple peripheral nodes), Mesh (nodes connected in a grid pattern), Ring (nodes connected in a closed loop), Fully Connected (every node connected to every other node), Bus (all nodes connected to a single central line), Tree (a hierarchical structure of nodes), and Line (nodes connected in a straight line). Below these is a 3D illustration of a star network with a central server and multiple client laptops.

FEEDBACK FROM 3/5

- **How does the distributed algorithm (slide 36) break a tie when two processes broadcast the same lamport clock value?**
- The distributed algorithm uses Lamport's logical clocks
- The distributed algorithm also requires a **total ordering of all events in the system**
 - This means we have to have a means to "order" all of the events so that it is unambiguous which actually happens first
- With total ordered multicasting, to break ties when logical clock values are the same for processes, we use the unique process IDs to break ties, and represent clock values using tuples instead of only logical clock values

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.6

6

BREAKING A LOGICAL CLOCK TIE WITH TUPLES

- Consider if p0 and p2 both want access to the shared resource
- But what if p0 and p2's logical clock values are both the same (=8)
- Using tuples, we express the clocks as:
 - $\langle 8, p0 \rangle$ and $\langle 8, p2 \rangle$
- Ties are broken by ordering the lower process IDs event as first
 - $p0 < p2$
- The distributed algorithm example does not use tuples for logical clocks for simplicity
- But if there was a tie, this is how it can be broken

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
 School of Engineering and Technology, University of Washington - Tacoma

L18.7

7

FEEDBACK - 2

- Can't multiple nodes get a simple majority of the votes? If there are 7 nodes and 2 make requests for the resource, won't the other 5 all reply with "OK", meaning both nodes would have OK's from more than half the nodes?
- Assume this question is for the distributed algorithm
- Distributed algorithm uses total ordered multicasting, and clock value ties are resolved by process ID
- When second node (p2) with higher logical clock (proc ID) requests access from the other node (p0) with lower logical clock (proc ID), the node with the higher logical clock (p2) will learn its clock is logically higher and yield to the node (p0) with the lower logical clock (proc ID).
 - p2 is blocked until p0 is done

SHORT-HAND-CODES FOR MEMBERSHIP TRACKING APPROACHES

- Include readme.txt or doc file with instructions in submission
- Must document membership tracking method

>> please indicate which types to test <<

ID	Description
F	Static file membership tracking – file is not reread
FD	Static file membership tracking DYNAMIC - file is periodically reread to refresh membership list
T	TCP membership tracking – servers are configured to refer to central membership server
U	UDP membership tracking - automatically discovers nodes with no configuration

CH. 6.4: ELECTION
ALGORITHMS

L18.24

24

ELECTION ALGORITHMS

- Many distributed systems require one process to act as a coordinator, initiator, or provide some special role
- Generally any node (or process) can take on the role
 - In some situations there are special requirements
 - Resource requirements: compute power, network capacity
 - Data: access to certain data/information
- Assumption:
 - Every node has access to a “node directory”
 - Process/node ID, IP address, port, etc.
 - Node directory may not know “current” node availability
- Goal of election: at conclusion all nodes agree on a coordinator or “leader”

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.25

25

ELECTION ALGORITHMS - 2

- Consider a distributed system with N processes (*or nodes*)
- Every process has an identifier $id(P)$
- Election algorithms attempt to locate the highest numbered process to designate as coordinator
- Algorithms:
 - Bully algorithm
 - Ring algorithm
 - Elections in wireless environments
 - Elections in large-scale systems

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.26

26

BULLY ALGORITHM

- When any process notices the coordinator is no longer responding to requests, it initiates an election
- Process P_k initiates an election as follows:
 1. P_k sends an ELECTION message to all processes with higher process IDs (P_{k+1} , P_{k+2} , ... P_{N-1})
 2. If no one responds, P_k wins the election and becomes coordinator
 3. If a “higher-up” process answers (P_{k+n}), it will take over and run the election. P_k will quit sending ELECTION messages.
- When the higher numbered process receives an ELECTION message from a lower-numbered colleague, it responds with “OK”, indicating it’s alive, and it takes over the election.

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.27

27

BULLY ALGORITHM - 2

- The higher numbered process then holds an election with only higher numbered processes (nodes).
- Eventually all processes give up except one, and the remaining process becomes the new coordinator.
- The coordinator announces victory by sending all processes a message stating it is starting as the coordinator.
- If a higher numbered node that was previously down comes back up, it holds an election, and ultimately takes over the coordinator role.
- The process with the “*biggest*” ID in town always wins.
- Hence the name, bully algorithm

School of Engineering and Technology, University of Washington - Tacoma

L18.29

BULLY ALGORITHM - 4

- **Requirement:** Every node knows who is participating in the distributed system
 - Each node has a group membership directory
- First process to notice the leader is offline launches a new election
- **GOAL:** Find the highest number node that is running
 - Loop over the nodes until the highest numbered node is found
 - May require multiple election rounds
- Highest numbered node is always the **"BULLY"**

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.30

RING ALGORITHM

- Election algorithm based on a network of nodes in logical ring
- Does not use a token
- Any process (P_k) starts the election by noticing the coordinator is not functioning
 1. P_k builds an election message, and sends to its successor in the ring
 - If successor is down, successor is skipped
 - Skips continue until a running process is found
 2. When the election message is passed around, each node adds its ID to a separate active node list
 3. When election message returns to P_k , P_k recognizes its own identifier in the active node list. Message is changed to COORDINATOR and “elected(P_k)” message is circulated.
 - Second message announces P_k is the NEW coordinator

March 7, 2024

TCCS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.31

31

RING: MULTIPLE ELECTION EXAMPLE

- **PROBLEM:** Two nodes start election at the same time: P_3 and P_6
- P_3 sends **ELECT(P_3)** message, P_6 sends **ELECT(P_6)** message
 - P_3 and P_6 both circulate ELECTION messages at the same time
- Also circulated with ELECT message is an active node list
- Each node adds itself to the active node list
- Each node votes for the highest numbered candidate
- P_6 wins the election because it's the candidate with the highest ID

March 7, 2024

TCCS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.32

32

RING ALGORITHM - DIFFERENCES

- Assumes nodes are organized in a ring, where each node has a known successor node
- Any node in the ring, *not necessarily the one with the highest ID*, can become the leader
- The membership list (**active node list**) is generated when circulating the ELECT message around the ring
 - Nodes do not have to maintain the membership list
 - ELECT message is simply circulated to the next node in the ring
- When multiple nodes conduct an election at the same time, the node with the higher ID wins

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.33

33

ELECTIONS WITH WIRELESS NETWORKS

- Assumptions made by traditional election algorithms not realistic for wireless environments:
 - >>> Message passing is reliable
 - >>> Topology of the network does not change
- A few protocols have been developed for elections in ad hoc wireless networks
- Vasudevan et al. [2004] solution handles failing nodes and partitioning networks.
 - Best leader can be elected, rather than just a random one

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.34

34

WIRELESS ELECTION - 3

- When multiple elections are initiated, nodes only join one
- Source node tags its ELECTION message with unique identifier, to uniquely identify the election.
- With minor adjustments protocol can operate when the network partitions, and when nodes join and leave

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.37

37

ELECTIONS FOR LARGE-SCALE SYSTEMS

- Large systems often require several nodes to serve as coordinators/leaders
- These nodes are considered *“super peers”*
- *Super peers* must meet operational requirements:
 1. Network latency from normal nodes to *super peers* must be low
 2. *Super peers* should be evenly distributed across the overlay network (ensures proper load balancing, availability)
 3. Must maintain set ratio of *super peers* to normal nodes
 4. *Super peers* must not serve *too many normal nodes*

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.38

38

ELECTIONS FOR DHT BASED SYSTEMS

- DHT-based systems use a bit-string to identify nodes
- **Basic Idea:** Reserve fraction of ID space for super peers
- Reserve first $k = \log_2(N)$ bits for super-peer IDs
- Assume $m=8$ bit ID to identify nodes, with $N=256$ possible nodes
- m =number of bits to identify every node ($m=8$)
- Reserve left-most k -bits of ID to identify super peers ($k=3$)
- **Example:** For a system with $m=8$ bit identifier (256 nodes), and $k=3$ keys per node
- Required number of super peers is $2^{(k - m)} \cdot N$, where N is the number of nodes, with $N=256$:
 - **8 total super peers required for 256 nodes**
 - ID (8-bits): 000|00000
 - left most bits identify super peers
 - right most bits identify local nodes

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.39

39

SUPER PEERS IN AN M-DIMENSIONAL SPACE

- Given an overlay network, the idea is to position superpeers throughout the network so they are evenly disbursed
- **Use tokens:**
 - Give N tokens to N randomly chosen nodes
 - No node can hold more than (1) token
 - Tokens are “repelling force”. Other tokens move away
 - All tokens exert the same repelling force
 - This automates token distribution across an overlay network

March 7, 2024

TCSS558: Applied Distributed Computing [Winter 2024]
School of Engineering and Technology, University of Washington - Tacoma

L18.40

40

OVERLAY TOKEN DISTRIBUTION

- Gossiping protocol is used to disseminate token location and force information across the network
- If forces acting on a node with a token exceed a threshold, token is moved away (sent to nodes farther away)
- Once nodes hold token for awhile they become superpeers

QUESTION 8: SYNCHRONIZATION

- In the Network Time Protocol, node A is a client that communicates with node B, which is an NTP server. The communication propagation delay is estimated with the formula:

$$\theta = \frac{(T_2 - T_1) + (T_3 - T_4)}{2}$$

- (a) What key assumption is made about the propagation delay between A and B?

QUESTION 8: SYNCHRONIZATION

- (b) When NTP is used to synchronize clocks of client computers, when client clocks are ahead of the NTP server due to clock skew, why do clients never set their local clock(s) backwards to match the time of the NTP server?
