# Tutorial 7 – Docker Tutorial

Disclaimer: Subject to updates as corrections are found Version 0.11

The purpose of tutorial #7 is to provide an introduction to Docker, cgroups, and resource isolation with containers. This tutorial should be completed using a Ubuntu system. Any of the following should be sufficient: a Ubuntu system (e.g. laptop), a Ubuntu Virtual Box, or an EC2 instance with Ubuntu. The system used as a Docker host should have exactly <u>2 CPU cores</u>, and access to at least 4 GB of memory. If using VirtualBox, the CPU settings can be adjusted as needed. If using EC2, an appropriate instance type can be selected. (e.g. c5.large)

**TO SUBMIT THIS TUTORIAL:** Answer the questions as best as possible based on the observations of performing the tests/activities as described. Submit answers as a PDF file in Canvas. Use Google Docs, or Microsoft Word to create a PDF file.

# Task 1 – Working with Docker, creating a Dockerfile

To start, log into your Ubuntu machine. If using an EC2 instance, a multi-core VM such as a c5.large/m5.large or better is recommended. EC2 instances should be created as spot instances. If wanting to "pause" the instance, a persistent spot request can be used.

## Install Docker on Ubuntu

Highlight the commands, and copy-and-paste to the VM: curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -

```
sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu
$(lsb_release -cs) stable"
```

# refresh sources
sudo apt update

# install packages
apt-cache policy docker-ce

sudo apt-get install -y docker-ce

#verify that docker is running
sudo systemctl status docker

The "Docker Application Container Engine" should show as running.

The Docker daemon, by default, uses an IPC socket to support interprocess-communication between processes on the same Docker host. The Docker daemon, by default, always runs as the **root** user. Consequently the Docker IPC socket is owned by the root user, and other users on the Linux system can only access this IPC socket using sudo. This means you will be required to preface all Docker commands with "sudo" on your system.

If you don't like this **default** behavior, please refer to this article to create a Docker group, and then run the Docker daemon using this group. Then add users to the Docker group to avoid requiring the use of "sudo":

## https://docs.docker.com/engine/install/linux-postinstall/

## This tutorial assumes the superuser root account will always be used. All docker commands are prefaced with "sudo".

If not wanting to configure the "docker" group, you can save from typing "sudo" for each command by assuming the role of superuser in your bash shell by typing: "sudo bash".

# Create a docker image for testing

The "Docker Hub" is a public repository of docker images. Many public images are provided which include installations of many different software packages.

The "sudo docker search" command enables searching the repository to look for images.

For example, you can search for Ubuntu 10.04 images (from 2010!!) using: sudo docker search ubuntu10

Trusted images will be marked as OFFICIAL. Be careful with other images.

Let's start by downloading the official "ubuntu" docker container image: sudo docker pull ubuntu

Verify that the image was downloaded by viewing local images:

sudo docker images -a

Next, make a local directory to store files which describe a new docker image.

mkdir docker\_test
cd docker\_test

Using a text editor such as vi, vim, pico, or nano, edit the file "Dockerfile" to describe a new Docker image based on ubuntu:

nano Dockerfile

# Test Dockerfile contents:

```
FROM ubuntu
RUN apt-get update
RUN apt-get install -y stress-ng
RUN apt-get install -y sysbench
COPY entrypoint_test.sh /
ENTRYPOINT ["/entrypoint_test.sh"]
CMD ["6000"]
```

Next, create a script called "entrypoint test.sh" under your docker\_test directory as follows:

```
#!/bin/bash
# test daemon - runs container continually as a task...
# Exits task and container when sleep time expires.
sleep=$1
echo "daemon up... sleep for=$1 seconds"
sleep $sleep
exit
```

You'll need to change permissions on this file. Give the owner execute permission: chmod u+x entrypoint\_test.sh

Next, build the docker container: sudo docker build -t stressng .

Check that the docker image was build locally: sudo docker images

Next launch the container as follows: sudo docker run -d --rm stressng

Check that the container is up. Make a note of the 'CONTAINER ID', the left-most column. sudo docker ps -a

Next, run the bash shell interactively as a second process inside this container: Find the container-id from the docker ps command. sudo docker exec -it <container-ID> bash

QUESTION 0. What computer are you using as a Docker Host for tutorial #7? IS this an EC2 instance? If so, what type? If not an ec2 instance, how many CPUs are available on the DockerHost for the tutorial? How much RAM is available? Please use the command 'lscpu' before running 'sudo docker exec' to check and report the number of CPUs. Please use the command 'free -m' to check MB memory free on the host.

Next, open a second ssh terminal to your Ubuntu machine. THIS TERMINAL SHOULD BE TO YOUR HOST, NOT INSIDE THE CONTAINER. Navigate to the directory as follows:

cd /sys/fs/cgroup/cpuacct/docker

Under the docker directory, find the unique identifier for your container. The Docker 'CONTAINER ID' noted above is an abbreviation of the first ~12 characters of the full ID. Match the first ~12 characters, and navigate to this directory:

#### cd <container-ID-long>

This directory will contain CPU metrics only for this container. Watch the "cpuacct.usage" file:

watch -n .5 cat cpuacct.usage

The cpu utilization is shown in nano seconds. Move the decimal 9 places to the left to convert to CPU seconds.

<u>QUESTION 1</u>. Without running any test, how much CPU time has transpired in seconds, since this container was created?

## Task 2 – Using Cgroups to monitor resource utilization

Print out the initial CPU utilization value (*or refer to the value in the "watch" terminal*): [>>In the Host window] cat cpuacet.usage

Next, run the stress-ng command:

[>>In the Docker window]
stress-ng --cpu 2 --cpu-method fft --cpu-ops 5000

Next, print out the updated current CPU utilization value: [>>In the Host window] cat cpuacct.usage

QUESTION 2. After running the test, what is the value of the CPU counter now?

<u>QUESTION 3.</u> What is the difference in CPU time in seconds that transpired for running the test? (subtract cputime2 – cputime1)

The output of stress-ng reports the runtime in seconds. This is considered "wall clock time".

<u>QUESTION 3B.</u> Observe the difference between the runtime that stress-ng reported (wall clock time), and the CPU time as measured by the linux cgroup cpuacct (time the task ran on the CPU)? Which is GREATER (*wall-clock-time* or *CPU-time*)?

Contemplate for a moment why either wall-clock-time or CPU-time is greater.

Before proceeding, try repeating the test, and explore various system metrics that are available under the **/sys/fs/cgroup/** directory. You may also explore running different stress-ng tests.

For help in stress-ng, see: <u>http://manpages.ubuntu.com/manpages/artful/man1/stress-ng.1.html</u> <u>https://wiki.ubuntu.com/Kernel/Reference/stress-ng</u> <u>https://www.cyberciti.biz/faq/stress-test-linux-unix-server-with-stress-ng/</u>

# Task 3 – Persisting Docker Images to "Docker Hub" image repository

Docker images are stored in "Docker Hub". Docker Hub can be compared to "GitHub". Where "GitHub" provides a repository for tracking changes to source code for one project, "DockerHub" provides a repository for tracking changes to a Docker container image. Just like GitHub, with DockerHub there are public and private repositories. DockerHub repositories are used to collect versions of a single image. These version can be tagged with names for quick retrieval. Free DockerHub accounts are limited to only one private repository of images, but they can have unlimited public repositories. So if wanting to maintain more the one private Docker image, it is necessary to upgrade beyond the basic DockerHub account.

To get started, you'll need to create an account on DockerHub. Using a web browser, navigate to:

https://hub.docker.com/

Next, create an account by completing the form:

Get Started Today for Free Already have an account? Sign In
Docker ID
Email
Password •
Send me occasional product updates and announcements.  I agree to the <u>Subscription Service Agreement</u> , <u>Privacy Policy</u> and <u>Data Processing Terms</u> . <u>Image a robot</u> <u>Exercise</u> <u>Exercise</u>
Sign Up

Please note your account information (Docker ID, email, password) for future use.

Once creating an account, using the GUI, create a new repository:

Click on the "Create Repository" button:

**Create Repository** 

Give the repository a name. Enter Name: tcss562\_f21 Choose to make the repository either public or private. Then press the **[CREATE]** button.

Now, log into your DockerHub account from the command line:

sudo docker login -u <USERNAME>

Inspect your IMAGE ID for your stressng Docker image

sudo docker images -a

Using the IMAGE ID, tag this image for adding into your DockerHub repository

sudo docker tag <IMAGE ID> <Docker Hub USERNAME>/tcss562\_f21:latest

Now commit the image to your public repository

sudo docker push <Docker Hub USERNAME>/tcss562\_f21

Now manually delete both the stressng image and the tagged image that you just committed to the DockerHub repository.

To remove the images, you'll need to make sure the container has exited. To kill the container, find it's ID using: sudo docker ps -a Then kill the container using: sudo docker kill <container-id>

Now remove all traces of the stressng image from your system sudo docker rmi stressng sudo docker rmi <Docker Hub USERNAME>/tcss562\_f21

Now using the DockerHub search command, look for the tcss562\_f21 repository

sudo docker search tcss562\_f21

You may see other students repositories here if they create public repositories.

Go ahead and PULL your pushed docker image, put preface the command with the Linux "time" command to record how long it takes.

time sudo docker pull <Docker Hub USERNAME>/tcss562\_f21

Now, purge this image:

sudo docker rmi <Docker Hub USERNAME>/tcss562

Next, rebuild your stressng container, but time how long it takes: time sudo docker build -t stressng . <u>QUESTION 4</u>. Is it faster to pull the docker image from DockerHub or rebuild the image from scratch locally? Please list the times for pulling vs. building.

#### Task 4 – Using Docker to constrain resource allocation

Next, exit the ssh session.

Now, assign the cpu-shares of the docker container:

sudo docker update --cpu-shares="128" <container-id>

Repeat the stress test: stress-ng --cpu 2 --cpu-method fft --cpu-ops 5000

**QUESTION 5.** What happens to the runtime of the test?

For question 4, based on the documentation, describe what we are seeing with respect to the runtime of stressng after assigning cpu-shares: <a href="https://docs.docker.com/config/containers/resource">https://docs.docker.com/config/containers/resource</a> constraints/#cpu

Next, reset the CPU shares to the default sudo docker update --cpu-shares="1024" <container-id>

And then assign the containers "cpus" sudo docker update -cpus=".5" <container-id>

Now, print out the cpuacct.usage before the test:

[>>In the Host window] cat cpuacct.usage

[>>In the Docker window]
Now, in the second window, repeat the stress test and observe the run time:
stress-ng --cpu 2 --cpu-method fft --cpu-ops 5000

Obtain the end cpu usage, and calculate the differences: [>>In the Host window] cat cpuacet.usage

#### **QUESTION 6.**

a. What was the CPU utilization for the test (report the number)? (subtract cputime2 – cputime1) b. How did it vary from our previous measurement (higher vs. lower)? c. In your own words, provide a *possible* explanation for this behavior. (qualitative grading)

Next, reset the CPU allocation for the container:

sudo docker update --cpus="2" <container-id>

## Task 3 – Test CPU Isolation with Docker

Now, in a second terminal window, create a second instance of the same container.

Launch the container as follows: sudo docker run -d --rm stressng

Check that the new container is up, and check for the new ID: sudo docker ps -a

Now, let's test CPU isolation of containizeration.

Assuming you're on a two-core system, first limit the CPU allocation to 1 core for each of the two containers.

Find the container IDs using the docker ps -a command.

```
And assign the CPU allocation for both containers:
sudo docker update --cpus="1" <container-id-A>
sudo docker update --cpus="1" <container-id-B>
```

Next, run a bash shell interactively on the second container: Use the container-id from the docker ps command above. sudo docker exec -it <container-ID> bash

In two separate terminals, for each of the containers, type the command, but DO NOT hit enter yet: stress-ng --cpu 2 --cpu-method fft --cpu-ops 5000

First, run one container alone to measure the stand-alone performance of the command.

Next, prepare to run the command in both commands in parllel. This requires submitting commands to both containers as close as possible in time so their execution overlaps as much as possible.

<u>QUESTION 7 CPU Isolation:</u> What is the <u>performance difference</u> when running the command standalone vs. running two instances at the same time when CPU allocation has been set to 1? For simplicity, report the performance difference for <u>container A</u>. To describe your difference calculation, provide the runtime in seconds observed when running <u>container A standalone</u>, and running <u>container A concurrently</u> at the same time as container B.

If container isolation is "perfect" for sharing the CPU, then performance should essentially be the same.

### Task 4 – Test Memory Isolation with Docker

Next, let's try a memory stress test to test for how well the Docker containers provide isolation from concurrent memory operations on the host.

In one of the terminals, run the sysbench command to stress memory.

sysbench --test=memory --memory-block-size=1M --memory-total-size=100G --numthreads=1 run

At the conclusion, look for the memory throughput value.

This is right below the "Total operations", and the throughput is shown in "MiB/sec". This represents the amount of memory that was transferred per second.

Now, stage this command to perform the memory stress test on two containers at the same time. Recall these two containers should have had their CPU's limited using the setting: --cpus="1"

Run the command at the same time in two containers: sysbench --test=memory --memory-block-size=1M --memory-total-size=100G --numthreads=1 run

If memory isolation is "perfect" for sharing the memory subsystem of the host, then performance should essentially be the same.

<u>QUESTION 8 Memory Isolation:</u> What is the memory <u>throughput</u> values (MiB/sec) for both containers A and B?

QUESTION 9 Memory Isolation: What is the average memory latency (in ms) for both containers A and B?

<u>QUESTION 10 Memory Isolation:</u> How did the memory throughput and memory latency change when comparing the standalone (1 container) test values with the concurrent container test?

QUESTION 11 Comparison:

(a) What was the % throughput/latency change for the sysbench memory test with 2 containers vs 1? (b) What was the % runtime change for the stress-ng CPU with 2 containers vs 1?

To answer this question, use the formulas to PROVIDE the difference between runtime (CPU isolation), and latency/throughput (Memory isolation).

> %diff<sub>runtime</sub> = (runtime<sub>2</sub> - runtime<sub>1</sub>) / runtime<sub>1</sub> %diff<sub>latency</sub> = (latency<sub>2</sub> - latency) / latency<sub>1</sub> %diff<sub>throughput</sub> = (throughput<sub>2</sub> - throughput<sub>1</sub>) / throughput<sub>1</sub>

## Task 5 – Cleanup

At the end of the tutorial, if using EC2, you may want to create an image of your virtual machine with Docker. If you haven't already, reimaging your server VM will allow it to be restored with minimal effort and setup in the future.

After reimaging, be sure to **<u>TERMINATE</u>** all EC2 instances. Failing to do so, could result in loss of AWS credits or AWS charges to a credit card.

You may also want to purge old duplicate snapshots, when you've created more than one image of an EBSbacked instance. It may not be worthwhile to keep old copies around when new images supersede them.
