Today:
- Interpreted vs. compiled languages
- Fortran

Wednesday:
- More Fortran
- Computer storage of numbers

Read: Class notes and references.

Compiled vs. interpreted language

Not so much a feature of language syntax as of how language is converted into machine instructions.

Many languages use elements of both.

Interpreter:
- Takes commands one at a time, converts into machine code, and executes.
- Allows interactive programming at a shell prompt, as in Python or Matlab.
- Can’t take advantage of optimizing over a entire program — does not know what instructions are coming next.
- Must translate each command while running the code, possibly many times over in a loop.

Compiled language

The program must be written in 1 or more files (source code).

These files are input data for the compiler, which is a computer program that analyzes the source code and converts it into object code.

The object code is then passed to a linker or loader that turns one or more objects into an executable.

Why two steps?

Object code contains symbols such as variables that may be defined in other objects. Linker resolves the symbols and coverts them into addresses in memory.

Often large programs consist of many separate files and/or library routines — don’t want to re-compile them all when only one is changed. (Later we’ll use Makefiles.)

Simple Fortran program

```fortran
! $CLASSHG/codes/fortran/example1.f90
program example1
  implicit none
  real (kind=8) :: x,y,z
  x = 3.d0
  y = 1.d-1
  z = x + y
  print *, "z = ", z
end program example1
```

Notes:
- Indentation optional (but make it readable!)
- First declaration of variables then executable statements
- implicit none means all variables must be declared
Simple Fortran program

! $CLASSHG/codes/fortran/example1.f90
program example1
  implicit none
  real (kind=8) :: x,y,z

  x = 3.d0
  y = 1.d-1
  z = x + y
  print *, "z = ", z
end program example1

More notes:
- (kind = 8) means 8-bytes used for storage,
- 3.d0 means $3 \times 10^0$ in double precision (8 bytes)
- 2.d-1 means $2 \times 10^{-1} = 0.2$

Compiling and running Fortran

Suppose example1.f90 contains this program.

Then:

$ gfortran example1.f90

compiles and links and creates an executable named example1.exe

To run the code after compiling it:

$ ./example1.exe

The command ./example1.exe executes this file (in the current directory).
Compile-time errors

Introduce an error in the code: (zz instead of z)

```fortran
program example1
  implicit none
  real (kind=8) :: x, y, z
  x = 3.d0
  y = 2.d-1
  zz = x + y
  print *, "z = ", z
end program example1
```

This gives an error when compiling:

```
$ gfortran example1.f90
example1.f90:11.6:
  zz = x + y
        1
Error: Symbol 'zz' at (1) has no IMPLICIT type
```

R.J. LeVeque, University of Washington | AMath 483/583, Lecture 4, April 4, 2011

Without the “implicit none”

Introduce an error in the code: (zz instead of z)

```fortran
program example1
  real (kind=8) :: x, y, z
  x = 3.d0
  y = 2.d-1
  zz = x + y
  print *, "z = ", z
end program example1
```

This compiles fine and gives the result:

```
$ gfortran example1.f90
$ ./a.out
  z = -3.626667641771191E-038
```

Or some other random nonsense since z was never set.

R.J. LeVeque, University of Washington | AMath 483/583, Lecture 4, April 4, 2011

Fortran types

Variables refer to particular storage location(s), must declare variable to be of a particular type and this won’t change.

The statement

```fortran
implicit none
```

means all variables must be explicitly declared.

Otherwise you can use a variable without prior declaration and the type will depend on what letter the name starts with.

Default:

- integer if starts with i, j, k, l, m, n
- real (kind=4) otherwise (single precision)

Many older Fortran codes use this convention!

Much safer to use `implicit none` for clarity, and to help avoid typos.

R.J. LeVeque, University of Washington | AMath 483/583, Lecture 4, April 4, 2011

Fortran arrays and loops

```fortran
! $CLASSHG/codes/fortran/loop1.f90
program loop1
  implicit none
  integer, parameter :: n = 10000
  real (kind=8), dimension(n) :: x, y
  integer :: i
  do i=1,n
    x(i) = 3.d0 * i
  enddo
  do i=1,n
    y(i) = 2.d0 * x(i)
  enddo
  print *, "Last y computed: ", y(n)
end program loop1
```

R.J. LeVeque, University of Washington | AMath 483/583, Lecture 4, April 4, 2011
Fortran arrays and loops

program loop1
    implicit none
    integer, parameter :: n = 10000
    real (kind=8), dimension(n) :: x, y
    integer :: i

Comments:
• integer, parameter means this value will not be changed.
• dimension(n) :: x, y means these are arrays of length n.

do i=1,n
    x(i) = 3.d0 * i
enddo

Comments:
• x(i) means i'th element of array.
• Instead of enddo, can also use labels...
do 100 i=1,n
    x(i) = 3.d0 * i
 100 continue

The number 100 is arbitrary. Useful for long loops. Often seen in older codes.

Fortran if-then-else

! $CLASSHG/codes/fortran/ifelse1.f90

program ifelse1
    implicit none
    real(kind=8) :: x
    integer :: i
    i = 3
    if (i<=2) then
        print *, "i is less or equal to 2"
    else if (i/=5) then
        print *, "i is greater than 2, not equal to 5"
    else
        print *, "i is equal to 5"
    endif
end program ifelse1

Booleans: .true. .false.

Comparisons:
< or .lt. <= or .le.
> or .gt. >= or .ge.
== or .eq. /= or .ne.

Examples:
(i >= 5) .and. (i < 12)
((i .lt. 5) .or. (i .ge. 12)) .and. &
(i .ne. 20)

Note: & is the Fortran continuation character. Statement continues on next line.
program boolean1
  implicit none
  integer :: i, k
  logical :: ever_zero
  ever_zero = .false.
  do i = 1, 10
    k = 3*i - 1
    ever_zero = (ever_zero .or. (k == 0))
  enddo
  if (ever_zero) then
    print *, "3*i - 1 takes the value 0 for some i"
  else
    print *, "3*i - 1 is never 0 for i tested"
  endif
end program boolean1

prior to Fortran, programs were often written in machine code or assembly language.

FORTRAN = FORmula TRANslator

Major changes in Fortran 77, which is still widely used.

Major changes again from Fortran 77 to Fortran 90.

Fortran 95: minor changes.

Fortran 2003: not fully implemented by most compilers.

We will use Fortran 90/95.

One big difference: Fortran 77 (and prior versions) required fixed format of lines:

Executable statements must start in column 7 or greater,

Only the first 72 columns are used, the rest ignored!
Fortran 90: free format.
Indentation is optional (but highly recommended).

`gfortran` will compile Fortran 77 or 90/95.
Use file extension `.f` for Fortran 77.
