Today:
- Array storage in Fortran
- Passing arrays to subroutines
- Fortran modules
- Multi-file Fortran codes

Wednesday:
- Makefile

Read: Class notes and references
There are several new Fortran sections.

Array storage

Rank 1 arrays have a single index, for example:

```fortran
real(kind=8) :: x(3)
real(kind=8), dimension(3) :: x
```

are equivalent ways to define $x$ with elements $x(1), x(2), x(3)$.

You can also specify a different starting index:

```fortran
real(kind=8) :: x(0:2), y(4:6), z(-2:0)
```

These are all arrays of length 3 and this would be a valid assignment:

```fortran
y(5) = z(-2)
```

Passing arrays to subroutines

This produces:

```
x = 5.00000000000000
y = 5.00000000000000
i = 1075052544
j = 0
```

Nasty!!

- The storage location of $x$ and the next 2 storage locations were all set to the floating point value 5.0e0
- This messed up the values originally stored in $y$, $i$, $j$.
- Integers are stored differently than floats. Two integers take up 8 bytes, the same as one float, so the assignment $a(3) = 5.$ overwrites both $i$ and $j$.
- The first half of the float 5., when interpreted as an integer, is huge.

Note: $x$ is a scalar, dummy argument $a$ is an array.
Passing arrays to subroutines

This compiles fine, but running it gives:

```
Segmentation fault
```

This means that the program tried to change a value of memory it was not allowed to.

Only a small amount of memory is devoted to the variables declared.

The memory we tried to access might be where the program itself is stored, or something related to another program that's running.

Segmentation faults

Debugging seg faults can be difficult.

Tips:

Compile using `-g` flag and then try running under `gdb`

```
$ gfortran -g arraypassing2.f90
$ gdb ./a.out
```

```
(gdb) run
Starting program: ./a.out
Program received signal SIGSEGV, Segmentation fault.
0x080488ce in setvals (a=Cannot access memory at address 0xbffff370) at arraypassing2.f90:27
27 a(i) = 5.
```

```
(gdb) where
#0 0x080488ce in setvals
#1 0x0804886a8 in arraypassing2 () at arraypassing2.f90:27
```

This tells us that the error occurred at line 27, and that the subroutine was called at line 13.
Segmentation faults

You can also probe the value of variables.
To find out what value of \(i\) it died on:

\[
\text{(gdb) print } i
\]
\$1 = 403

This tells us that the error occurred when trying to set \(a(403)\).
Why not when \(i = 4\)?
Memory is organized into pages and integer multiples of pages must be devoted to variables in the program.
Apparently a page contains \(8 \times 402 = 3216\) bytes.

Fortran debuggers

gdb does not work very well!!
Unfortunately there's no good open source debugger for Fortran.
Commercial options include totalview.

Rank 2 arrays

An array of rank 2 has two indices, e.g.

\[
\text{real(kind=8)} :: A(3,4)
\]

Compiler must map the 12 array elements to memory locations.
Different languages use different conventions!
In Fortran, arrays are stored by column in memory, so the 12 consecutive memory locations would correspond to:

\[
A(1,1) \\
A(2,1) \\
A(3,1) \\
A(1,2) \\
A(2,2) \\
\ldots \\
A(1,4) \\
A(2,4) \\
A(3,4)
\]

Note: equivalence statement \(\Rightarrow\) same memory locations for \(A\) and \(B\).
Also note implied do loops and format statements.
Rank 2 arrays

Output:
Row 1 of A contains: 10.0 40.0 70.0 100.0
Row 1 is in locations 1 4 7 10
These elements of B contain: 10.0 40.0 70.0 100.0
Row 2 of A contains: 20.0 50.0 80.0 110.0
Row 2 is in locations 2 5 8 11
These elements of B contain: 20.0 50.0 80.0 110.0
Row 3 of A contains: 30.0 60.0 90.0 120.0
Row 3 is in locations 3 6 9 12
These elements of B contain: 30.0 60.0 90.0 120.0

Splitting Fortran codes into files

Split into 3 files:
Main program...
! $CLASSHG/codes/fortran/multifile1/main.f90
program demo
  print *, "In main program"
  call sub1()
  call sub2()
end program demo

and two separate files (for \( N = 1, 2 \)):

! $CLASSHG/codes/fortran/multifile1/subN.f90
subroutine subN()
  print *, "In subN"
end subroutine subN

Compile all three and link together into single executable:
$ gfortran main.f90 sub1.f90 sub2.f90 \
-o fullcode.exe

Run the executable:
$ ./fullcode.exe
In main program
In sub1
In sub2
**Splitting Fortran codes into files**

Can split into separate compile....

$ gfortran -c main.f90 sub1.f90 sub2.f90

$ ls *.o
main.o sub1.o sub2.o

... and link steps:

$ gfortran main.o sub1.o sub2.o -o fullcode.exe

$ ./fullcode.exe
In main program
In sub1
In sub2

**Advantage:** If we modify sub2.f90 to print "Now in sub2" we only need to recompile this piece:

$ gfortran -c sub2.f90

$ gfortran main.o sub1.o sub2.o -o fullcode.exe

$ ./fullcode.exe
In main program
In sub1
Now in sub2

When working on a big code (e.g. 100,000 lines split between 200 subroutines) this can make a big difference!

Next lecture: Make this easier with Makefiles.

**Fortran modules**

General structure of a module:

module <MODULE-NAME>
  ! Declare variables
contains
  ! Define subroutines or functions
end module <MODULE-NAME>

A program or subroutine can use this module:

program <NAME>
  use <MODULE-NAME>
  ! Declare variables
  ! Executable statements
end program <NAME>

**Fortran module example**

! $CLASSHG/codes/fortran/multifile2/sub1m.f90
module sub1m
  contains
  subroutine sub1()
    print *, "In sub1"
  end subroutine sub1
end module sub1m

! $CLASSHG/codes/fortran/multifile2/main.f90
program demo
  use sub1m
  print *, "In main program"
call sub1()
end program demo
Fortran modules

Some uses:

- Can define global variables in modules to be used in several different routines.

  In Fortran 77 this had to be done with common blocks — much less elegant.

- Subroutine/function interface information is generated to aid in checking that proper arguments are passed.

  It’s often best to put all subroutines and functions in modules for this reason.

- Can define new data types to be used in several routines.

Compiling Fortran modules

If sub1m.f90 is a module, then compiling it creates sub1m.o and also sub1m.mod:

$ gfortran -c sub1m.f90

$ ls
main.f90 sub1m.f90 sub1m.mod sub1m.o

the module must be compiled before any subroutine or program that uses it!

$ rm -f sub1m.mod
$ gfortran main.f90 sub1m.f90
main.f90:5.13:
    use sub1m
    1
    Fatal Error: Can’t open module file ’sub1m.mod’ for reading at (1): No such file or directory

Another module example

Running this gives:

pi = 3.14159265358979
area for a circle of radius 2: 12.5663706143592

Another module example

Running this gives:

pi = 3.14159265358979
area for a circle of radius 2: 12.5663706143592
