## **OUTLINE:**

- 1. Introduction: the white-noise (Gaussian) problems**
  - Problem A: Estimator; monotone case.
  - Problem B: Likelihood ratio test; monotone case.
  - Problem C: Estimator; convex case.
- 2. Estimator; monotone case**
- 3. Likelihood ratio test; monotone case**
- 4. Estimator; convex case**
- 5. Further Problems**

## 1. Introduction: the white-noise (Gaussian) problems

### Problem A. Monotone function in white noise: estimation

- $\{W(t) : t \in R\}$  be two-sided Brownian motion starting from 0;
- $dW(t) =$  “white noise” .
- Observe  $X(t)$ ,  $t \in [-c, c]$  or  $t \in (-\infty, \infty)$  where

$$\begin{aligned}dX(t) &= f(t)dt + \sigma dW(t) \\ &= \text{“monotone function”} + \text{“white noise”} ; \\ X(t) &= F(t) + \sigma W(t) .\end{aligned}$$

- Problem: estimate  $f$ .
- Likelihood: via Cameron-Martin

$$\frac{dP_{f,\sigma}}{dP_{0,\sigma}} = \exp \left( \int_{-c}^c f(t)dX(t) - \frac{1}{2} \int_{-c}^c f^2(t)dt \right) .$$

The MLE  $\hat{f}_c$  of  $f$  maximizes

$$(1) \int_{-c}^c f(t) dX(t) - \frac{1}{2} \int_{-c}^c f^2(t) dt$$

over monotone functions  $f$ . Equivalently,  $\hat{f}_c$  minimizes

$$(2) \int_{-c}^c f^2(t) dt - 2 \int_{-c}^c f(t) dX(t)$$

“ = ”  $\int_{-c}^c (f(t) - x(t))^2 dt - \int_{-c}^c x^2(t) dt$

where  $x(t) = dX(t)/dt$  doesn't exist!

**Problem B. Monotone function in white noise, testing:**

- Observe

$$\begin{aligned}dX(t) &= f(t)dt + \sigma dW(t) \\ &= \text{“monotone function”} + \text{“white noise”}\end{aligned}$$

as in Problem A.

- Problem: test  $H_0 : f(t_0) = \theta_0$  versus  $H_1 : f(t_0) \neq \theta_0$ .  
Without loss, take  $t_0 = 0, \theta_0 = 0$ .

**Step 1:** The *constrained* MLE  $\hat{f}_c^0$  of  $f$  maximizes (1) subject to the constraint  $f(0) = 0$ .

**Step 2:** The likelihood ratio statistic is

$$\lambda_{c,\sigma} \equiv \frac{\sup_{f \in \mathcal{F}_c} dP_{f,\sigma}/dP_{0,\sigma}}{\sup_{f \in \mathcal{F}_c, f(0)=0} dP_{f,\sigma}/dP_{0,\sigma}} = \frac{dP_{\hat{f}_c,\sigma}/dP_{0,\sigma}}{dP_{\hat{f}_c^0,\sigma}/dP_{0,\sigma}}$$

**Problem:** Distribution of  $2 \log \lambda_{c,\sigma}$ ?  
Distribution of  $\lim_{\sigma \rightarrow 0} 2 \log \lambda_{c,\sigma}$ ?

### Problem C. Convex function in white noise: estimation

- $\{W(t) : t \in R\}$  be two-sided Brownian motion starting from 0;
- $dW(t) =$  “white noise” .
- Observe  $X(t)$ ,  $t \in [-c, c]$  or  $t \in (-\infty, \infty)$  where
$$dX(t) = f(t)dt + \sigma dW(t)$$
$$= \text{“convex function”} + \text{“white noise”} .$$
- Problem: estimate  $f$ .
- Likelihood: via Cameron-Martin

$$\frac{dP_{f,\sigma}}{dP_{0,\sigma}} = \exp \left( \int_{-c}^c f(t)dX(t) - \frac{1}{2} \int_{-c}^c f^2(t)dt \right) .$$

## 2. Estimator; monotone case (Problem A)

Let  $\|g\|_c \equiv \sup_{t \in [-c, c]} |g(t)|$ .

$\mathcal{F}_c = \{f : [-c, c] \mapsto R \mid f \text{ is monotone } \nearrow, \|f\|_c \leq K\}$ .

For  $f \in \mathcal{F}_c$ , set

$$F(t) = \begin{cases} \int_0^t f(s) ds, & t \geq 0 \\ -\int_t^0 f(s) ds, & t \leq 0. \end{cases}$$

**Theorem 1.**  $\hat{f}_c$  is the Maximum Likelihood Estimator of  $f$  in  $\mathcal{F}_c$  (and the Least Squares Estimator) if and only if:

- (i)  $\lambda_2 + \int_t^c d\{\hat{F}_c(u) - X(u)\} \geq 0$  for all  $t \in (-c, c]$ ;
- (ii)  $-K(\lambda_1 + \lambda_2) - \int_{-c}^c \hat{f}_c(u) d\{\hat{F}_c(u) - X(u)\} = 0$ ;
- (iii)  $\lambda_1 - \lambda_2 - \int_{-c}^c d\{\hat{F}_c(u) - X(u)\} = 0$ .

In fact

$$\lambda_1 = \int_{\{u: \hat{f}_c(u) = -K\}} d\{\hat{F}_c(u) - X(u)\}$$

$$\lambda_2 = \int_{\{u: \hat{f}_c(u) = K\}} d\{\hat{F}_c(u) - X(u)\}.$$

**Question:**

$$\lim_{c \rightarrow \infty} \widehat{f}_c(t) = ???$$

Special case:  $f_0(t) = 2t$ ,  $F_0(t) = t^2$ .

**Theorem 2.** For  $X \sim P_{f_0}$  on  $(-\infty, \infty)$ , there is a uniquely defined random continuous function  $\widehat{F} = \widehat{F}_\infty$  satisfying the following conditions:

- (i)  $\widehat{F}(t) \leq X(t)$  for each  $t \in R$ .
- (ii)  $\widehat{F}$  has a monotone (left) derivative  $\widehat{f}$ .
- (iii)  $\widehat{F}$  satisfies

$$\int_R \{X(t) - \widehat{F}(t)\} d\widehat{f}(t) = 0.$$

$\widehat{F} =$  the greatest convex minorant of  $X(t) = W(t) + t^2$ .  
 $\widehat{f} \equiv \mathbb{S}$  the slope process of the greatest convex minorant  $\widehat{F}$ .

**Question(s):**

1. What is the distribution of the process  $\widehat{f}$ ?
2. What is the distribution of  $\widehat{f}(0)$ ?

**Answers to 1 and 2:**

Groeneboom (1985) and (1988)!  
Groeneboom and Wellner (2000).

### 3. Likelihood ratio test: the monotone case (Problem B)

**Theorem 3.** There exists an almost surely uniquely defined random continuous function  $\widehat{F}^0$  on  $(-\infty, 0)$  and  $(0, \infty)$  (and one jump at 0) satisfying the following conditions:

- (i)  $\widehat{F}^0(t) \leq X(t)$  for each  $t \in R$ .
- (ii)  $\widehat{F}^0$  has a monotone (left) derivative  $\widehat{f}^0$  satisfying  $\widehat{f}^0(0) = 0$ .
- (iii)  $\widehat{F}^0$  satisfies

$$\int_R \{X(t) - \widehat{F}^0(t)\} d\widehat{f}^0(t) = 0.$$

In fact,  $\widehat{F}^0$  is (are) the *constrained greatest convex minorant(s)* of  $X(t) = t^2 + W(t)$ , and  $\widehat{f}^0 \equiv \mathbb{S}^0$  is the corresponding *slope process(es)*.

Recall that

$$\lambda_{c,\sigma} \equiv \frac{\sup_{f \in \mathcal{F}_c} dP_{f,\sigma}/dP_{0,\sigma}}{\sup_{f \in \mathcal{F}_c, f(0)=0} dP_{f,\sigma}/dP_{0,\sigma}} = \frac{dP_{\widehat{f}_c,\sigma}/dP_{0,\sigma}}{dP_{\widehat{f}_c^0,\sigma}/dP_{0,\sigma}}$$

**Theorem 4.** (Banerjee and Wellner, 2000). Suppose that  $f$  satisfies  $f(0) = 0$  and  $f'(0) > 0$ . Under  $X \sim P_{f,\sigma}$ ,

$$2 \log \lambda_{c,\sigma} \rightarrow_d \mathbb{D} = \int \{(\mathbb{S}(z))^2 - (\mathbb{S}^0(z))^2\} dz$$

as  $\sigma \rightarrow 0$ .

**Proof sketch:** By Brownian scaling and approximation of  $f$  in a neighborhood of 0 by a linear function, the problem reduces to finding the limit of  $2 \log \lambda_{c,1}$  as  $c \rightarrow \infty$  under the canonical monotone function  $f_0(t) = 2t$ . Then we have

$$\begin{aligned}
2 \log \lambda_{c,1} &= 2 \left\{ \int_{-c}^c \widehat{f}_c dX - \frac{1}{2} \int_{-c}^c \widehat{f}_c^2 dt \right. \\
&\quad \left. - \int_{-c}^c \widehat{f}_c^0 dX - \frac{1}{2} \int_{-c}^c (\widehat{f}_c^0)^2 dt \right\} \\
&= 2 \int_{-c}^c (\widehat{f}_c - \widehat{f}_c^0) dX - \int_{-c}^c \{\widehat{f}_c^2 - \widehat{f}_c^{02}\} dt \\
(3) \quad &\rightarrow 2 \int_{-\infty}^{\infty} (\widehat{f} - \widehat{f}^0) dX - \int_{-\infty}^{\infty} \{\widehat{f}^2 - \widehat{f}^{02}\} dt
\end{aligned}$$

where  $\widehat{f}$  and  $\widehat{f}^0$  are characterized by Theorems 2 and 3 respectively. Thus

$$\int (X - \widehat{F}) d\widehat{f} = 0 \quad \text{and} \quad \int (X - \widehat{F}^0) d\widehat{f}^0 = 0;$$

Thus via integration by parts,

$$\int (\widehat{f} - \widehat{f}_0) dX = \int \{\widehat{f}^2 - \widehat{f}^{02}\} dt,$$

and using this in (3) shows that the limit equals

$$\int_{-\infty}^{\infty} \{\widehat{f}^2 - \widehat{f}^{02}\} dt = \int \{ \{S(t)\}^2 - \{S^0(t)\}^2 \} dt \equiv \mathbb{D}.$$

**Question 3:** What is the distribution of  $\mathbb{D}$ ?

Only Monte-carlo evidence so far: Banerjee and Wellner (2000).

#### 4. Estimator; convex case (Problem C)

Let  $\|g\|_c \equiv \sup_{t \in [-c, c]} |g(t)|$ .

$\mathcal{F}_c = \{f : [-c, c] \mapsto \mathbb{R} \mid f \text{ is convex, } f(-c) = k_1, f(c) = k_2\}$ .

For  $f \in \mathcal{F}_c$ , set

$$F(t) = \begin{cases} \int_0^t f(s) ds, & t \geq 0 \\ -\int_t^0 f(s) ds, & t \leq 0, \end{cases}$$

and

$$H(t) = \begin{cases} \int_0^t F(s) ds = \int_0^t \int_0^s f(u) du ds, & t \geq 0 \\ -\int_t^0 F(s) ds = -\int_t^0 \int_s^0 f(u) du ds, & t \leq 0, \end{cases}$$

For the canonical convex function  $f_0(t) = 12t^2$ ,

$F_0(t) = 4t^3$ ,  $H_0(t) = t^4$ .

We also define

$$Y(t) \equiv \int_0^t X(s) ds = \int_0^t W(s) ds + H(t)$$

where now

$$\begin{aligned} dX(t) &= f(t) + dW(t) \\ &= \text{“convex”} + \text{“white noise”}. \end{aligned}$$

**Theorem 5.**  $\hat{f}_c$  is the Maximum Likelihood Estimator (MLE) (and the Least Squares Estimator) over  $\mathcal{F}_c$  if and only if:

- (i)  $\hat{H}_c(t) \geq Y(t)$  for  $t \in [-c, c]$ ;
- (ii)  $\int_{(-c,c)} (\hat{H}(t) - Y(t)) d\hat{f}'_c(t) = 0$ ;
- (iii)  $\hat{f}(-c) = k_1, \hat{f}(c) = k_2$ .

**Question:**

$$\lim_{c \rightarrow \infty} \hat{f}_c(t) = ???$$

Special case:

$$f_0(t) = 12t^2, F_0(t) = 4t^3, H_0(t) = t^4.$$

**Theorem 6.** For  $X \sim P_{f_0}$  on  $(-\infty, \infty)$ , there is a uniquely defined random continuous function  $\hat{H} = \hat{H}_\infty$  satisfying the following conditions:

- (i)  $\hat{H}(t) \geq Y(t)$  for each  $t \in R$ .
- (ii)  $\hat{H}$  has a convex second derivative  $\hat{f}$ .
- (iii)  $\hat{H}$  satisfies

$$\int_R \{\hat{H}(t) - Y(t)\} d\hat{H}^{(3)}(t) = 0.$$

$\widehat{H}$  = the “invelope process” of  $Y$ , is piecewise cubic;  
 $\widehat{F} = \widehat{H}'$  is piecewise quadratic;  
 $\widehat{f} = \widehat{H}''$  is piecewise linear (and convex);  
 $\widehat{f}' = \widehat{H}^{(3)}$  is piecewise constant (and “estimates”  $f_0'(t) = 24t$ ).

**Questions:**

4. What is the distribution of the process  $\widehat{f}$ ?
5. What is the distribution of  $\widehat{f}(0)$ ?
6. What is the joint distribution of  $(\widehat{f}(0), \widehat{f}'(0))$ ?

**No answers to 4-6 yet.**

Figure 1: Greatest Convex Minorant and  $W(t) + t^2$ .

Figure 2: One-Sided Greatest Convex Minorants and  $W(t) + t^2$ .

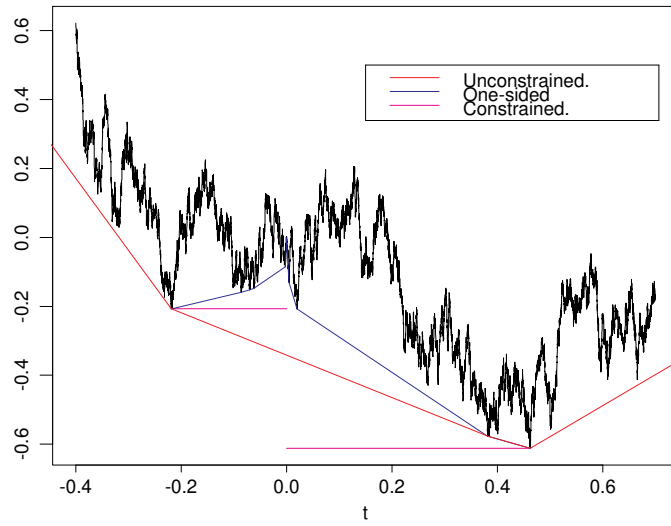

Figure 3: Close-up view of  $G_{1,1}$ ,  $\tilde{G}_{L,R}$ ,  $G_{1,1}^0$ , and  $W(t) + t^2$ .

## 5. Further Problems.

**Question 3.** Can we find the distribution of  $\mathbb{D}$  analytically? (Likelihood ratio statistic)

**Question 4.** What is the distribution of the process  $\hat{f}$ ? (convex function estimation)

**Question 5.** What is the distribution of  $\hat{f}(0)$ ? (convex function estimation)

**Question 6.** What is the joint distribution of  $(\hat{f}(0), \hat{f}'(0))$ ? (convex function estimation)

**Question 7.** What is the likelihood ratio test for testing  $f(t_0) = \theta_0$  in the convex function case?

**Question 8.** How can we prove that the same limit  $\mathbb{D}$  arises as the limit distribution for the likelihood ratio test for a large class of such problems involving monotone functions?

**Question 9.** What is the appropriate contiguity theory? What is the limit distribution of the likelihood ratio statistic under local alternatives?

**Question 10.** What about further smoothness restrictions? (Completely monotone?)
