Kessler, W.S. and S. Cravatte, 2013: Mean circulation of the Coral Sea. *J.Geophys.Res.*, submitted.

With thanks to Stuart Godfrey, Ernest Frohlich,  
and CSIRO Hobart .... who started me on this path in 2001

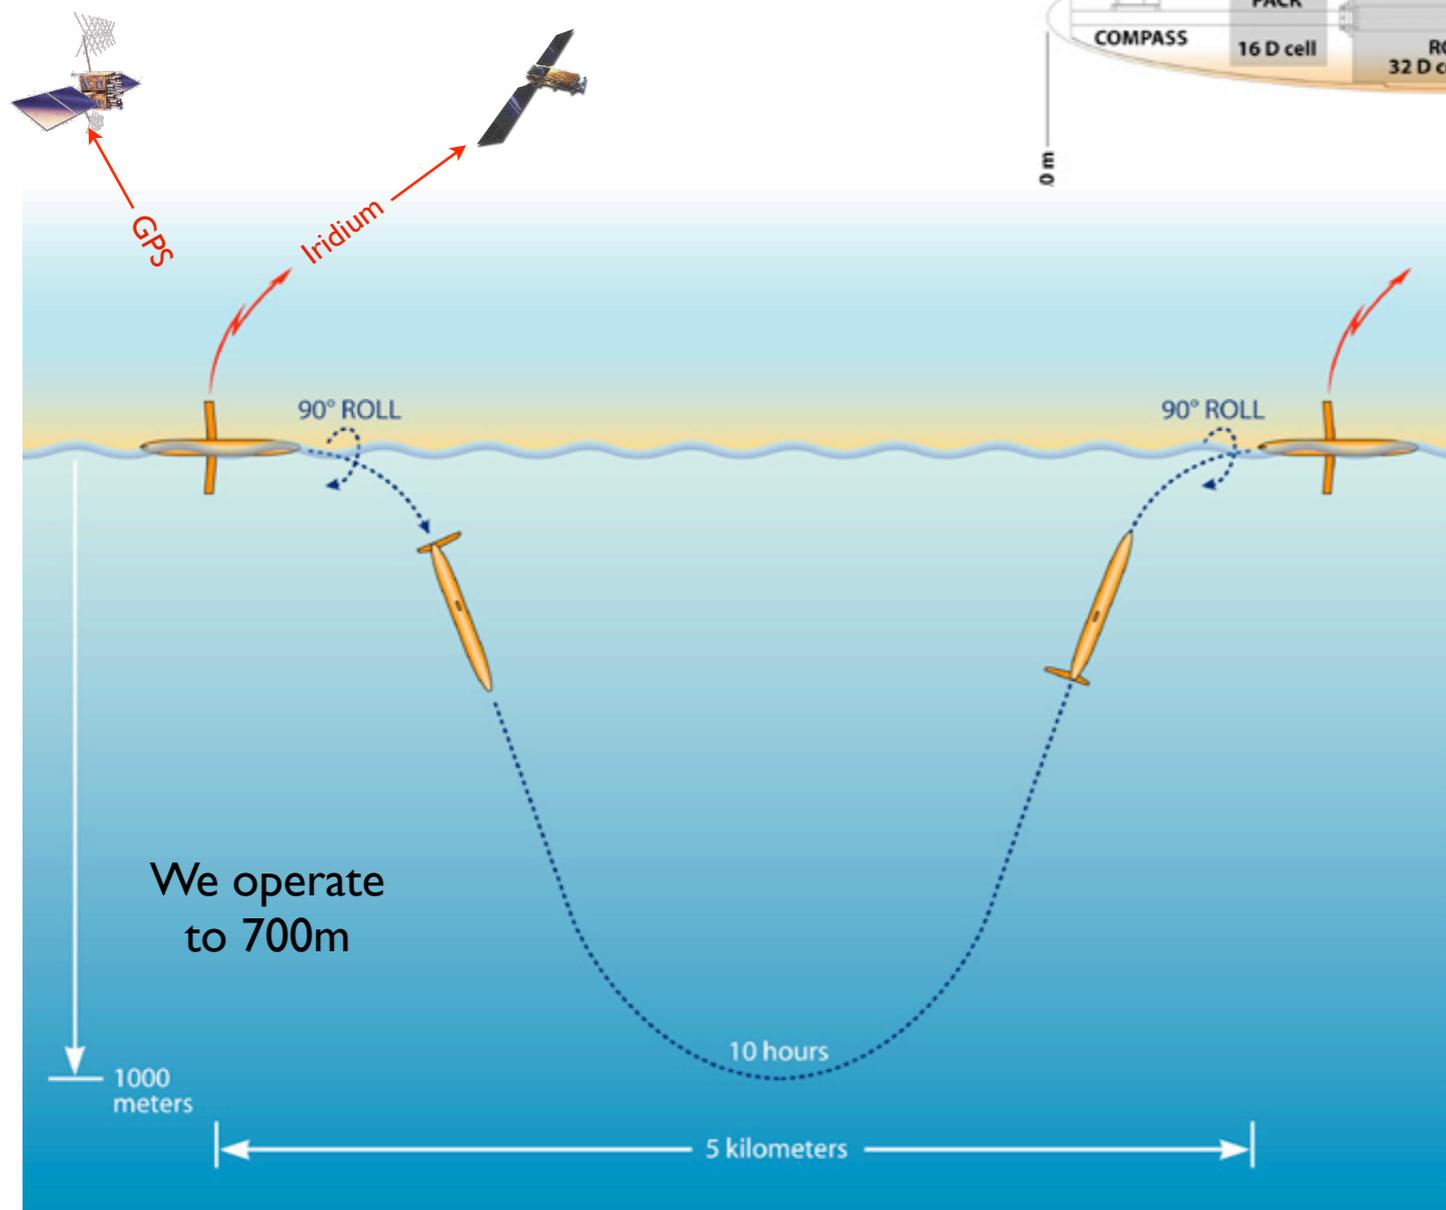

## Collaborators:

- Solomon Islands Meteorological Service
- University of Papua New Guinea
- Bureau of Meteorology (Australia)

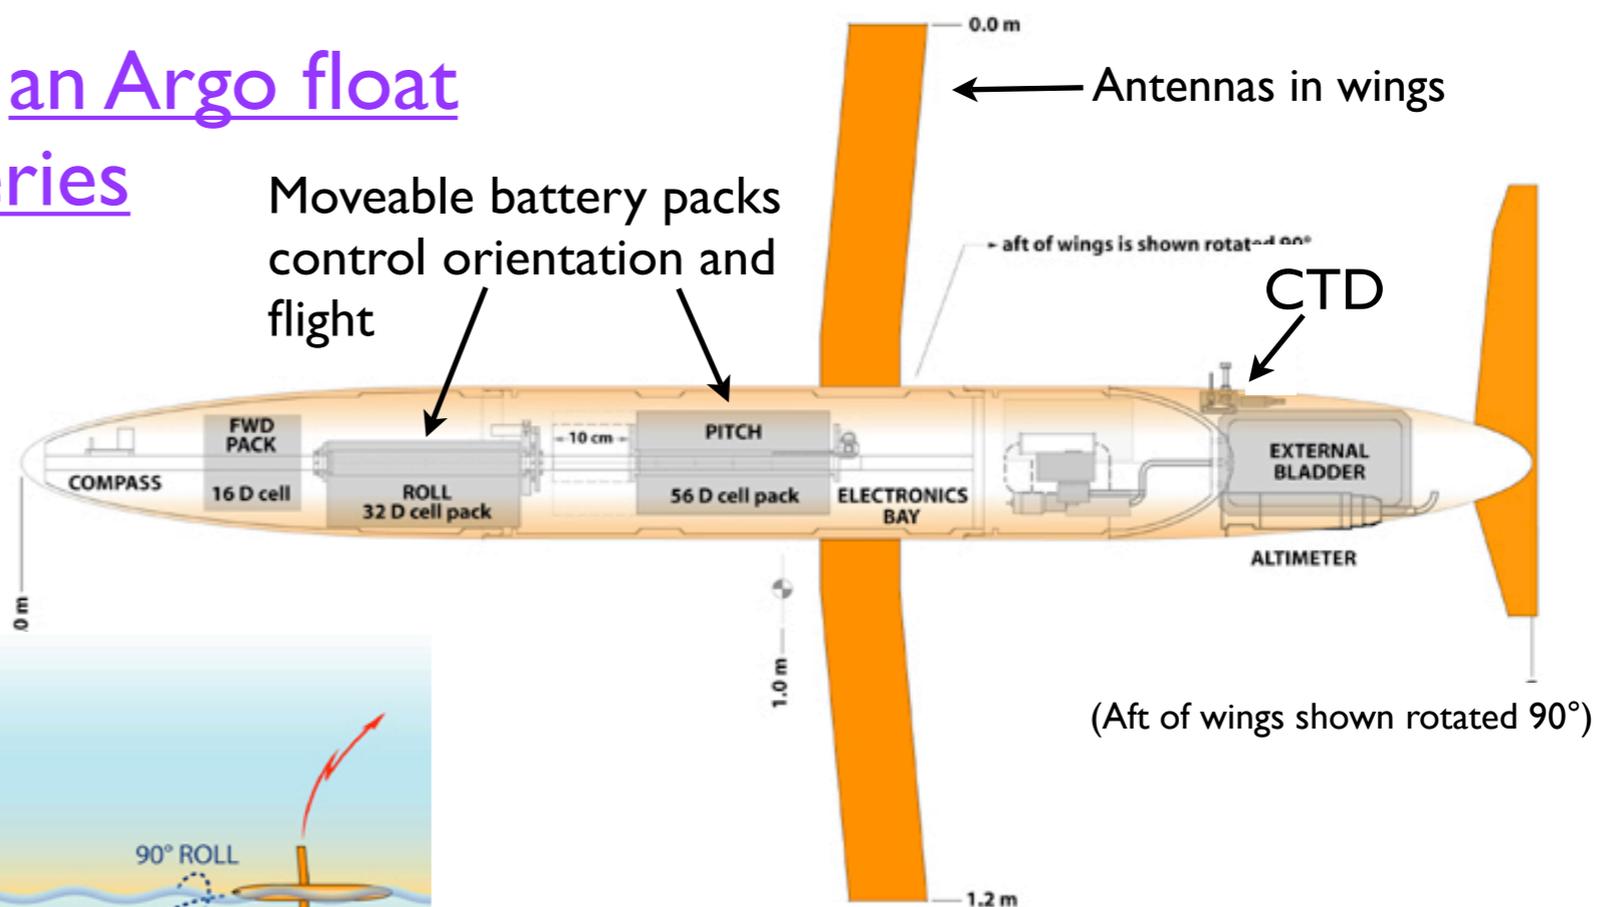

# The Spray glider is essentially an Argo float with wings and movable batteries

The Spray glider is developed and built by the Instrument Development Group at Scripps.

← 3 km (3-4 hr) →

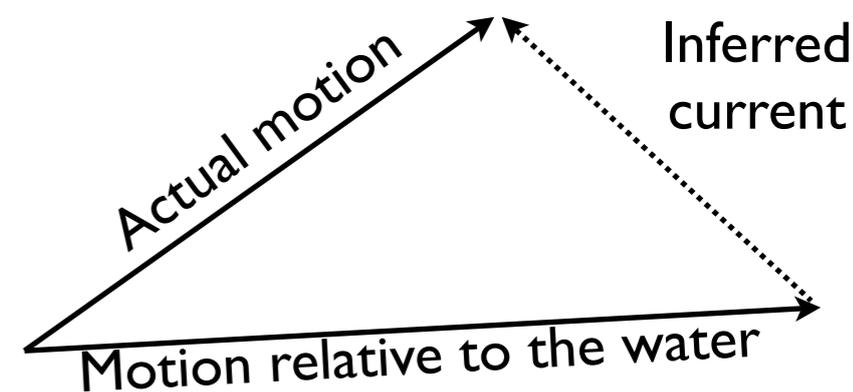

Range 4-5 months at 20 cm/s = 2000+km

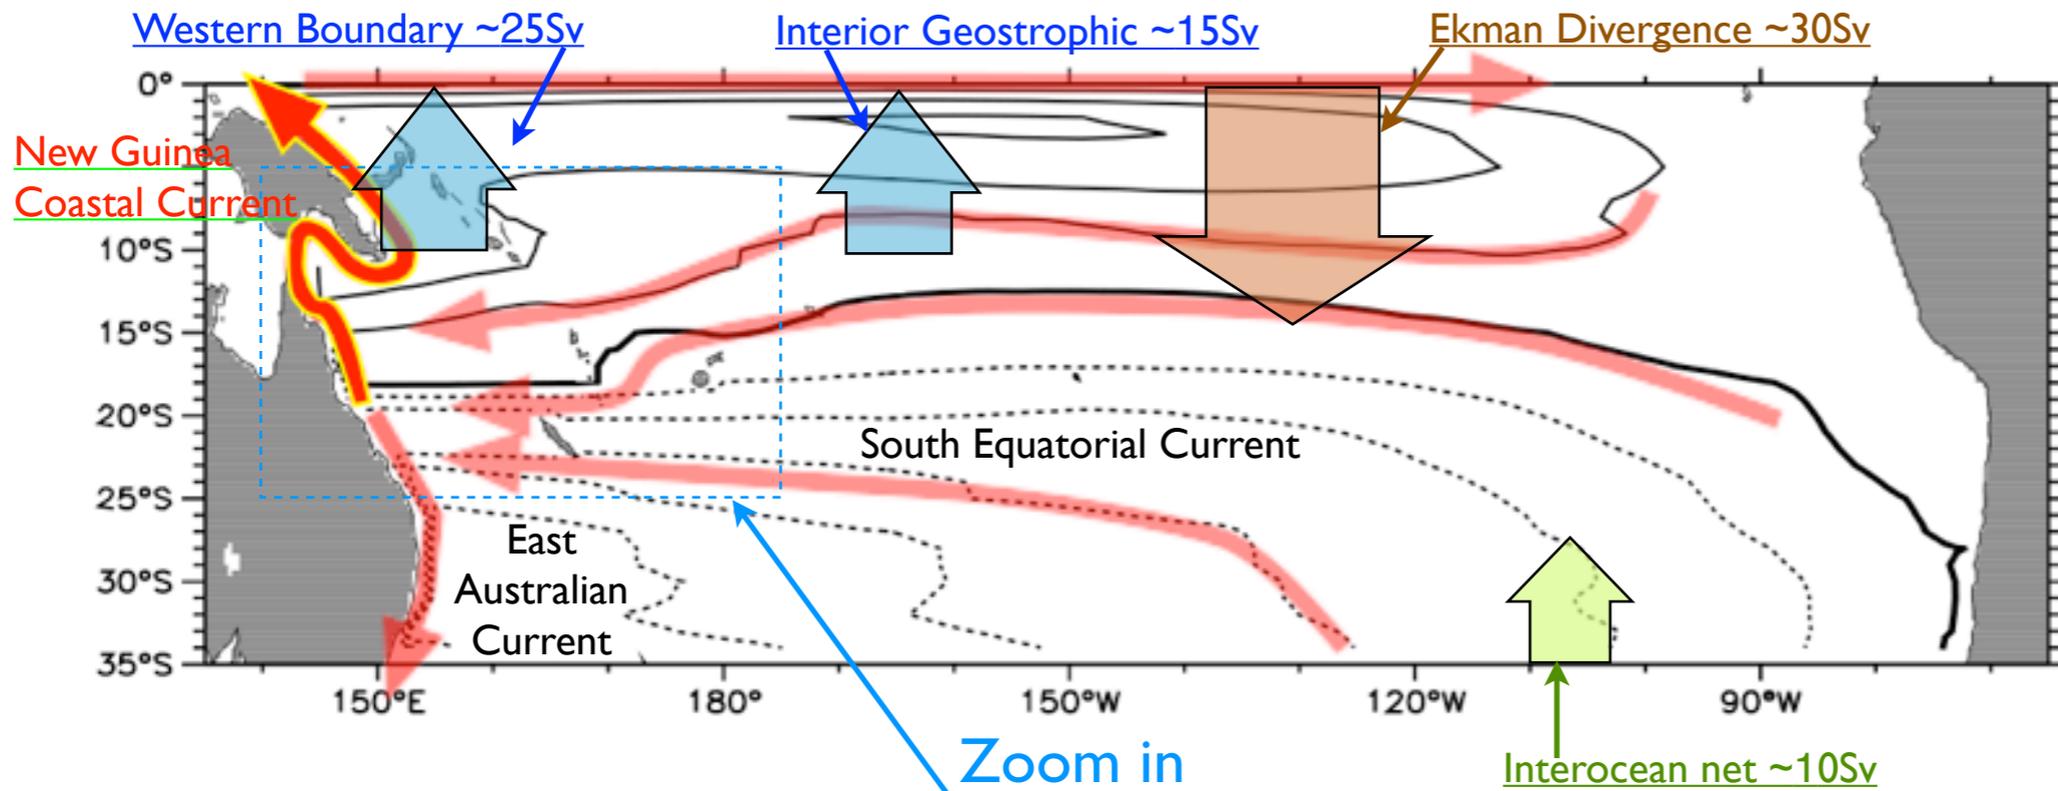

Very dense sampling (~ resolve tides)

Argo-comparable T-S profiles:  
geostrophic relative currents

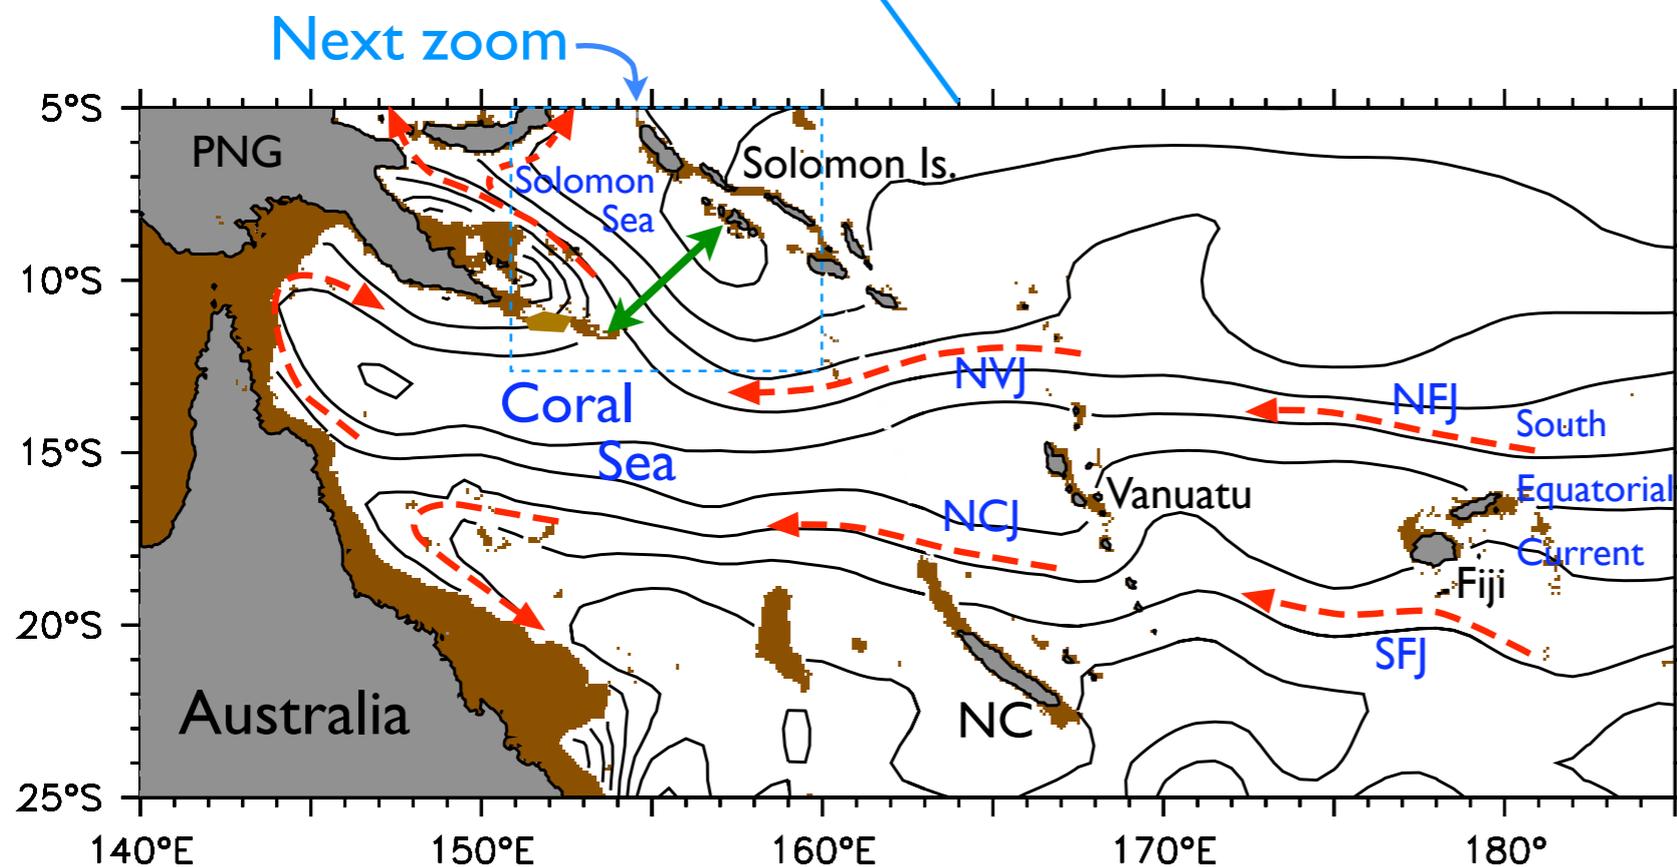

Infer vertical-average absolute currents  
by the glider's drift:

# South Pacific average circulation

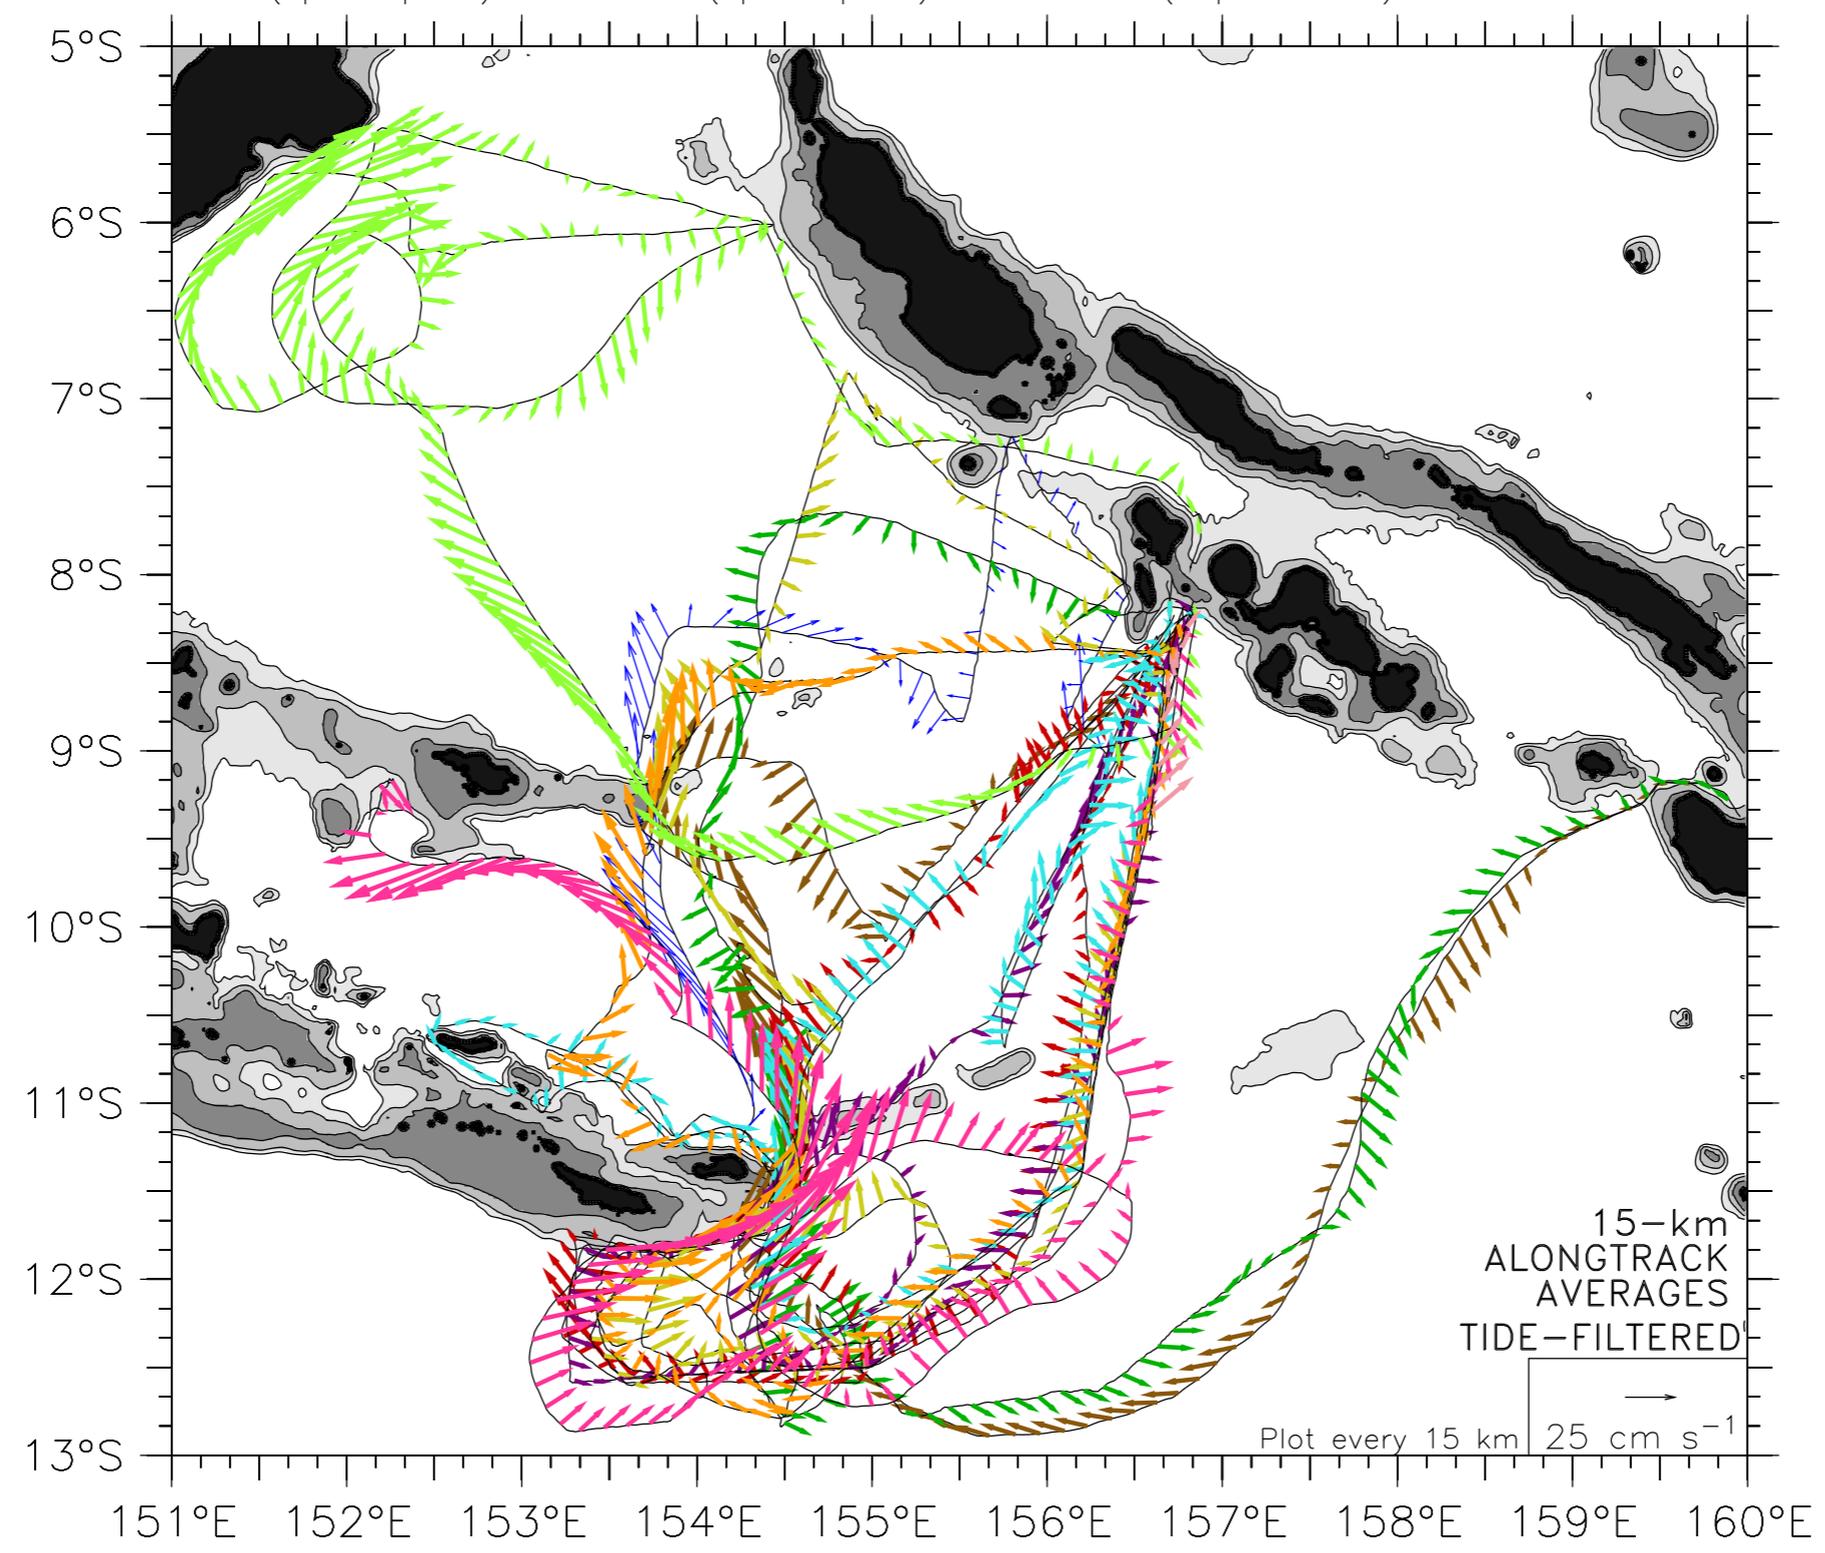

Island Rule  
(ERS winds)

Glider experiments  
cross the Solomon Sea  
and measure the flow  
towards the equator.

AVERAGES  
TIDE-FILTERED

From SEC

# Vertical-average currents at the tip of PNG

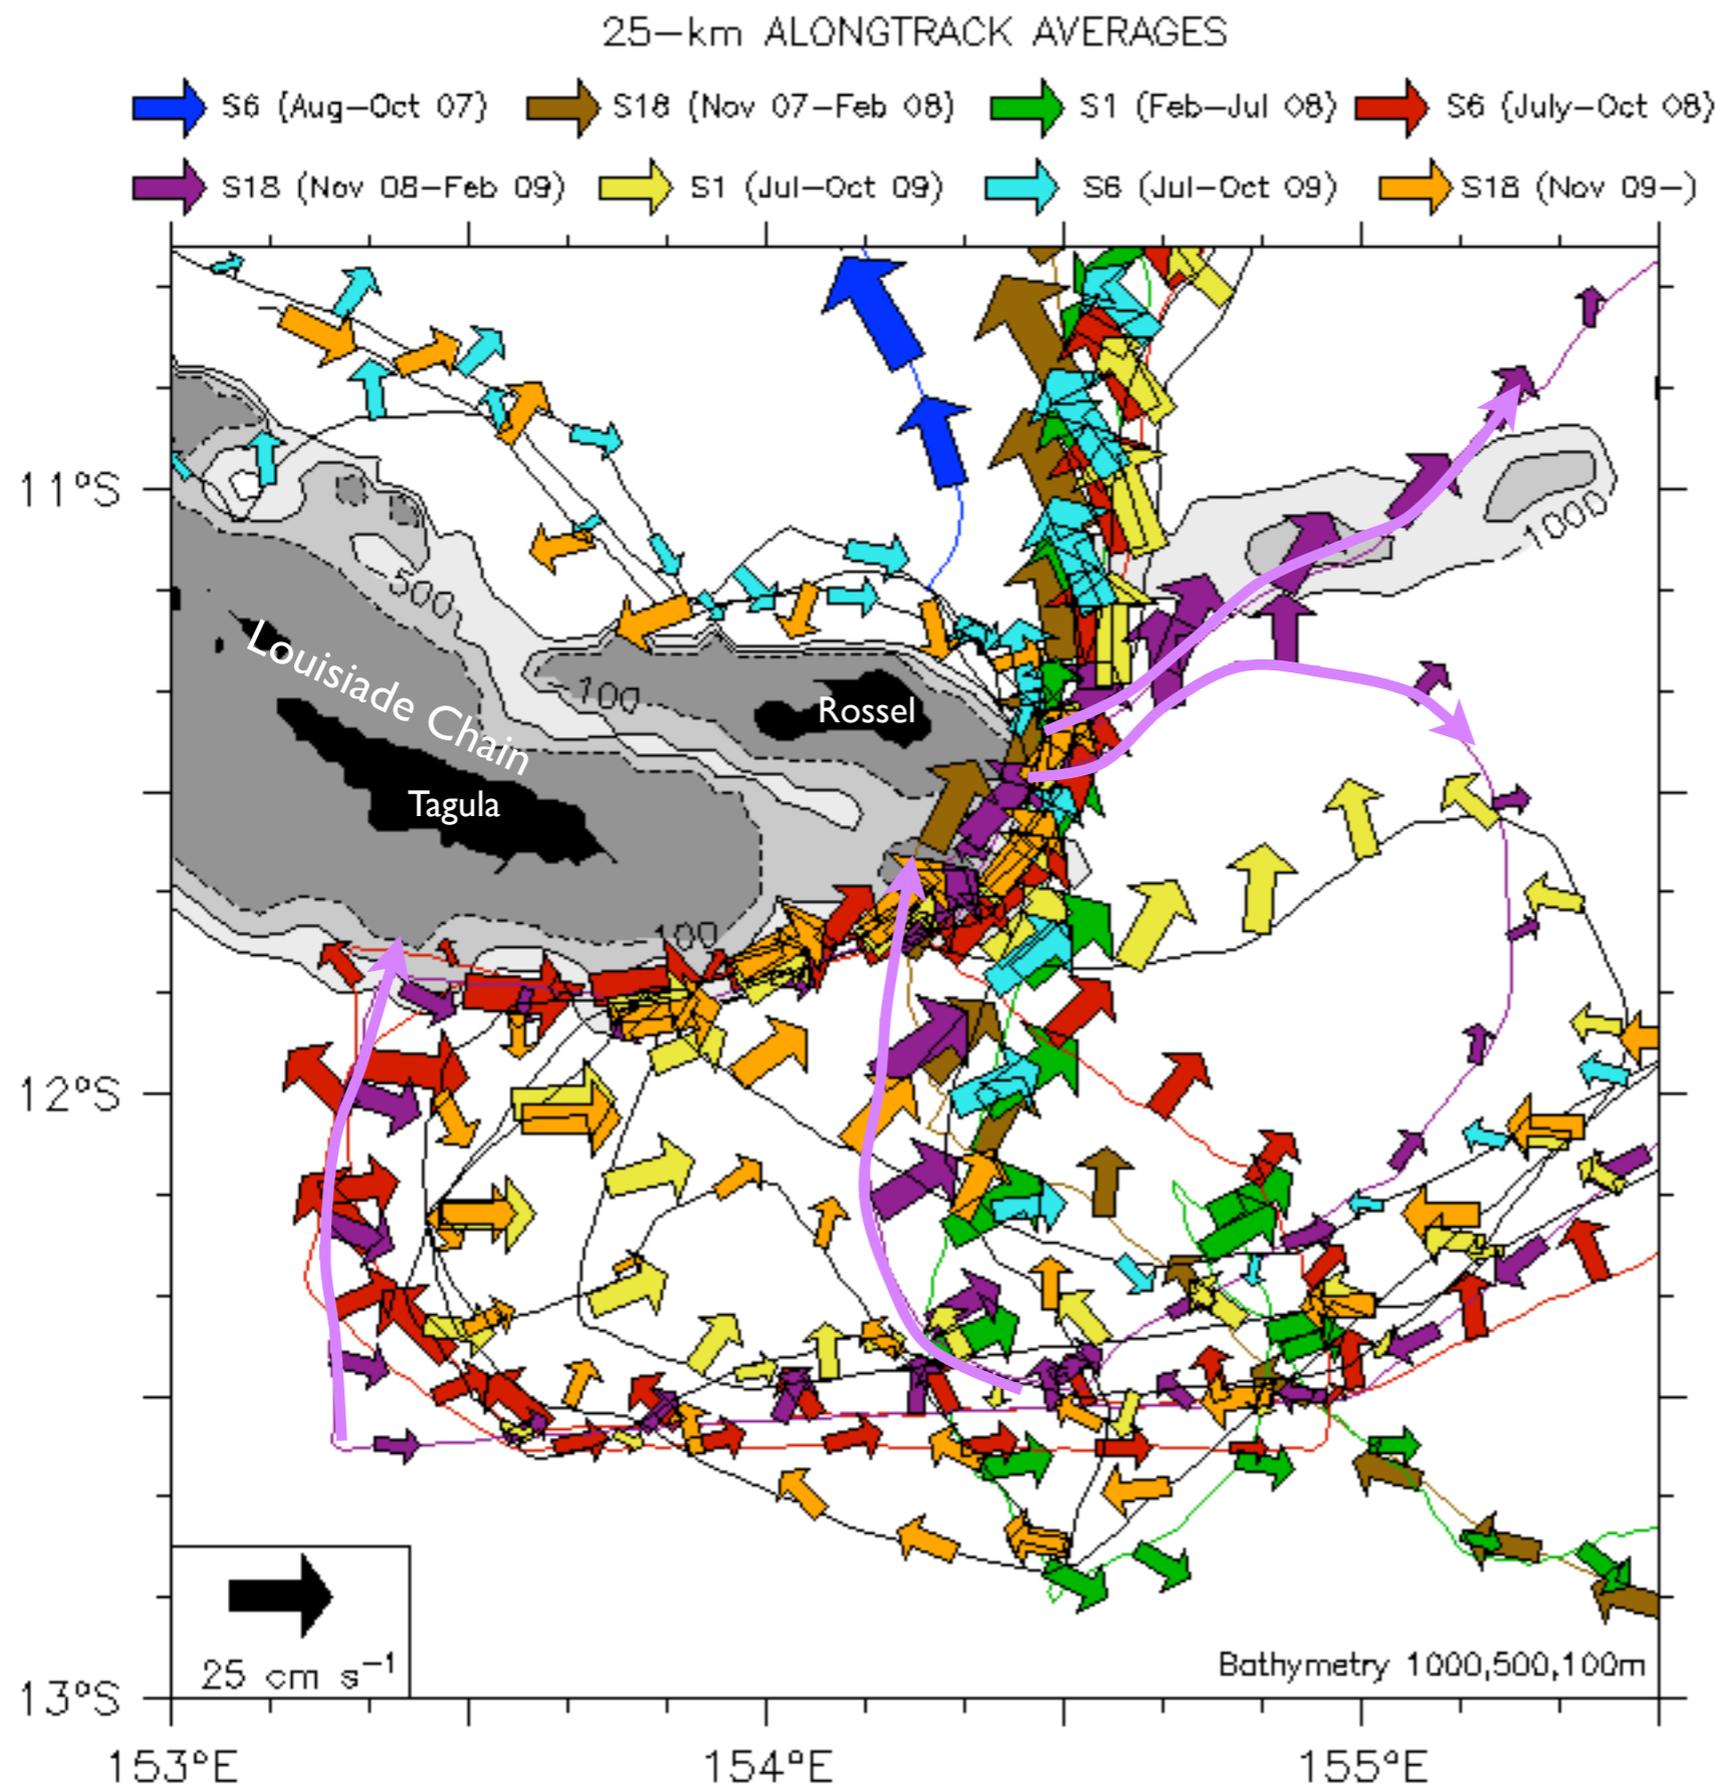

The most consistent observation is a strong current towards the equator at the tip of the Louisiades.

The current is very close to the reef line.

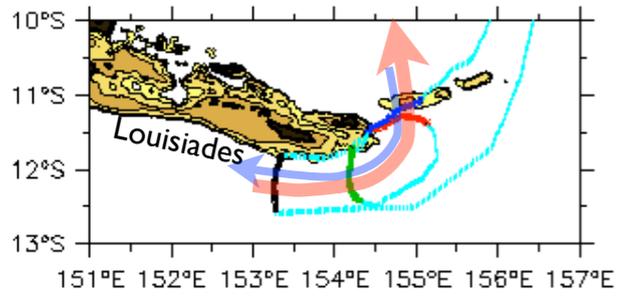

# Vertical-average currents at the tip of PNG

Now, we'll look at the vertical structure of the NGCU ... four 100km sections (light purple lines)

NGCU within 85km of the coast

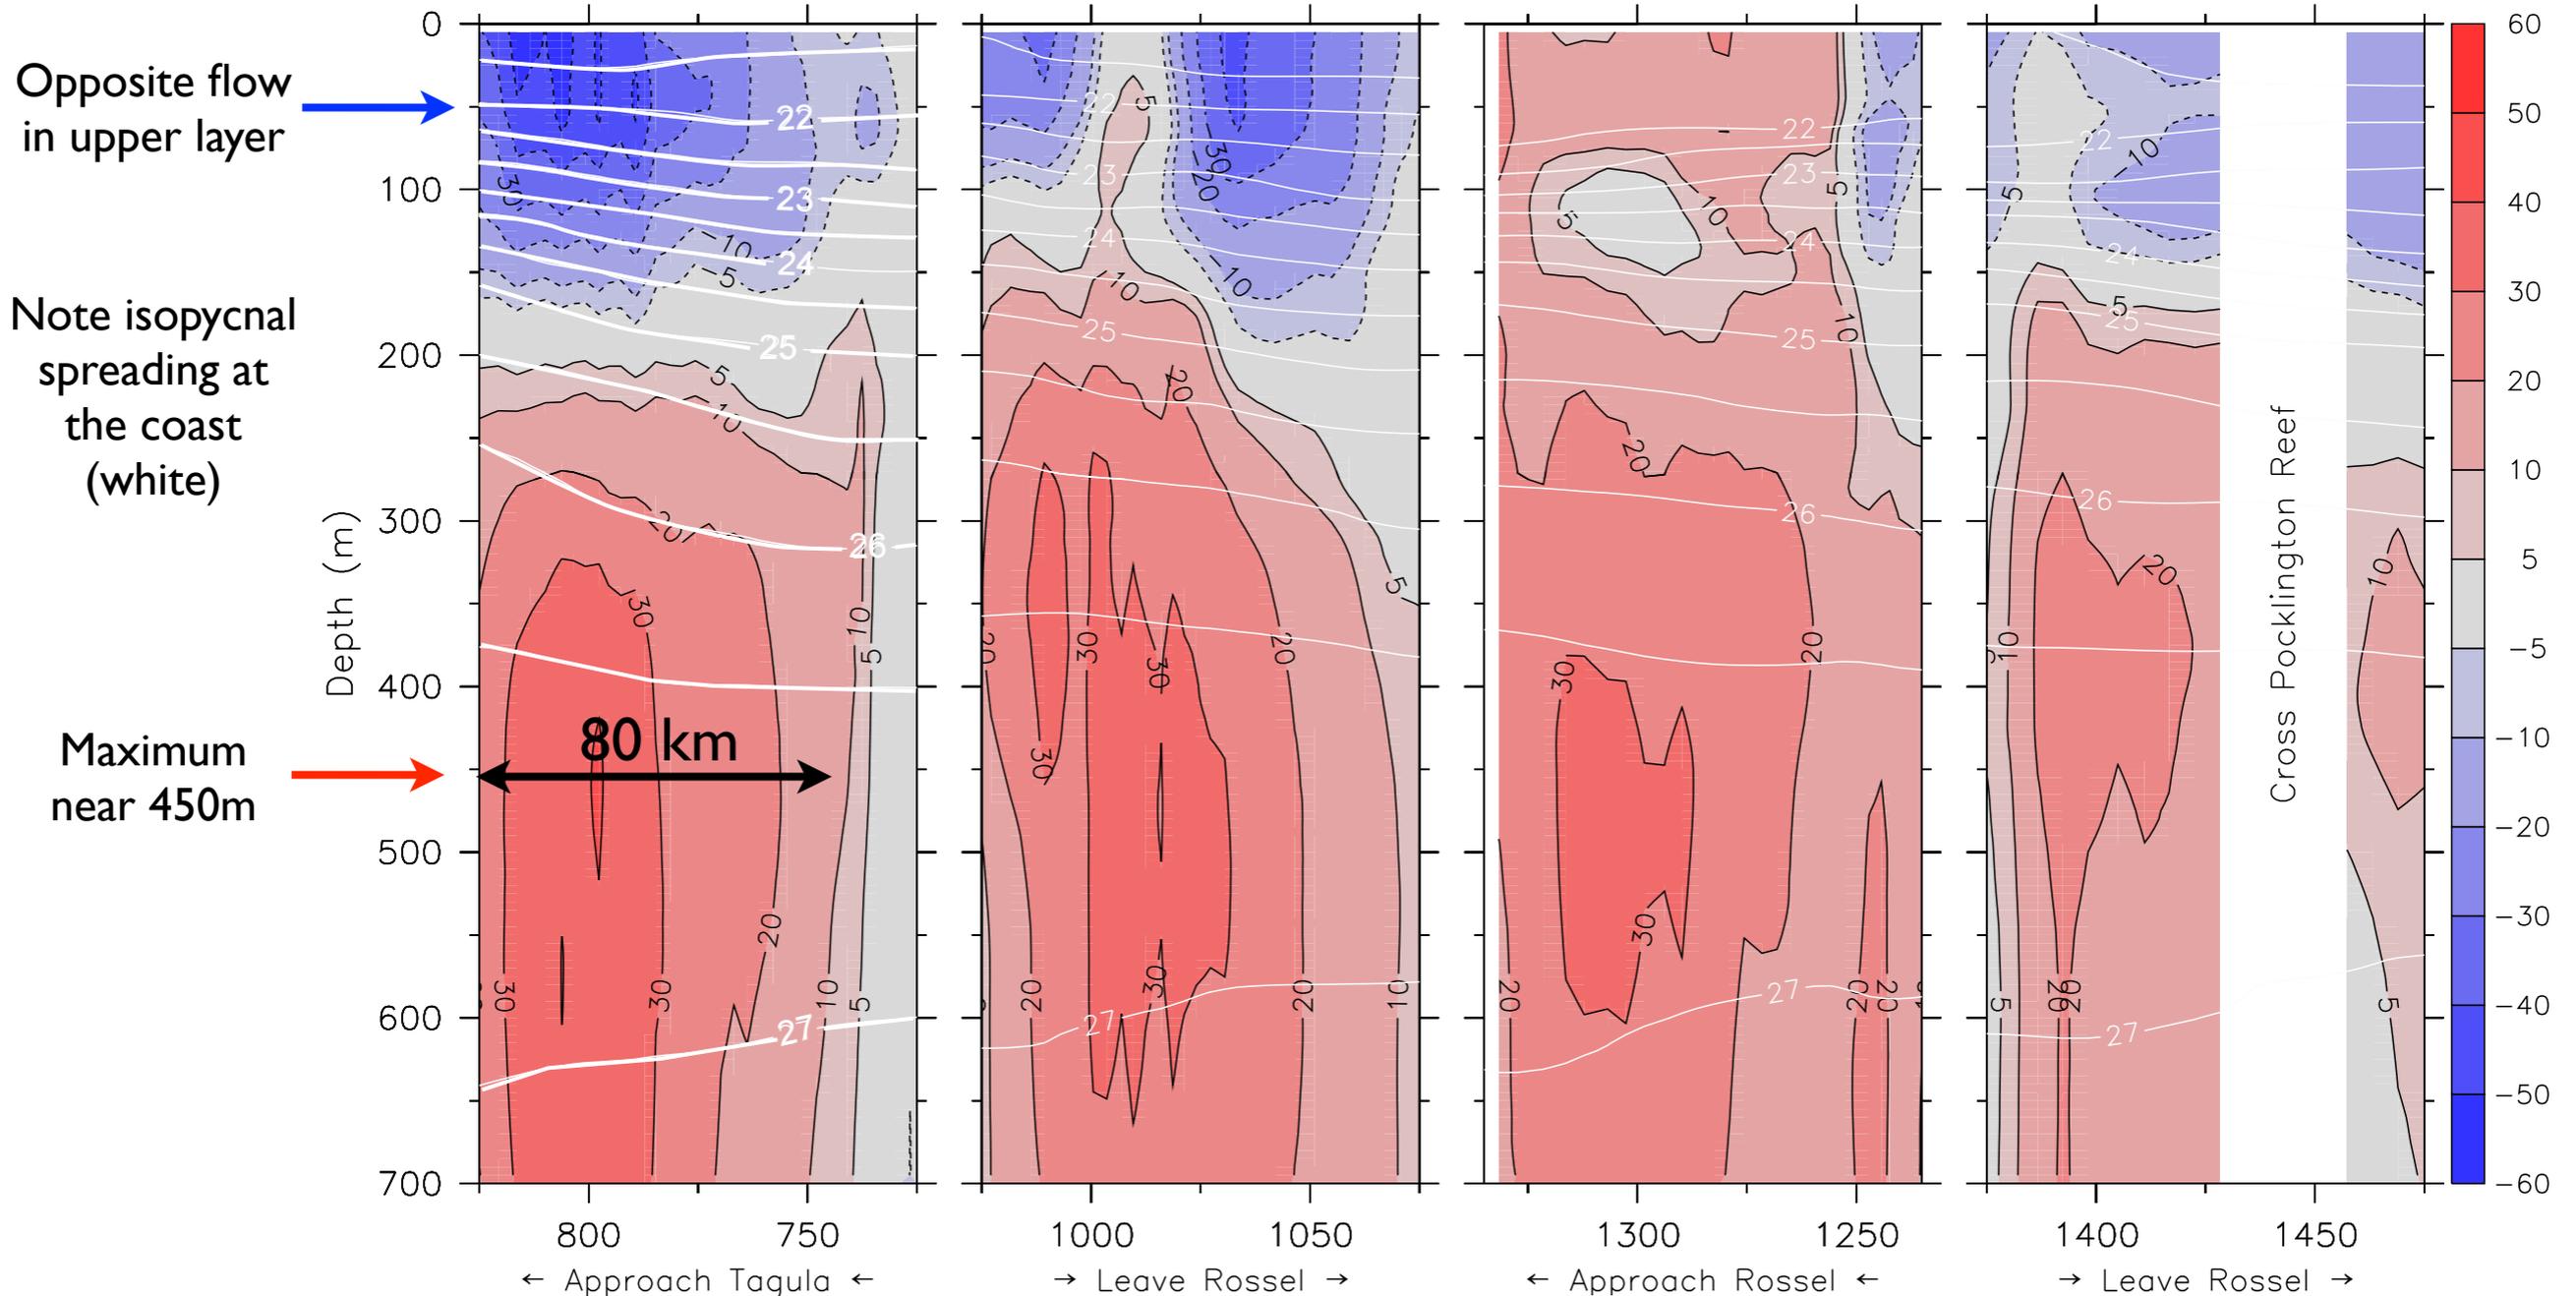

4 sections during Dec 08–Jan 09 (sn18)

# The equatorward flow is an undercurrent

## Currents at the tip of the Louisiades

Each section shows 100km from the coast on the left. Glider obs Dec 08-Jan 09

Positive (red) = Equatorward

# How to be quantitative with the irregularly-distributed glider tracks?

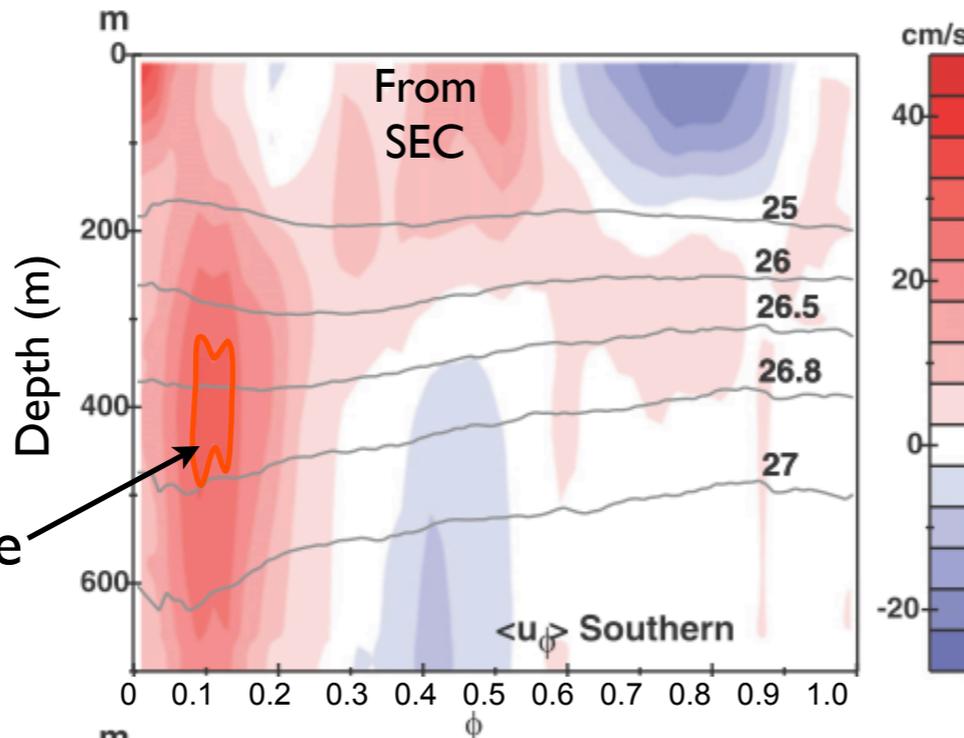

Define a function  $\Phi$ , such that:  $\nabla^2\Phi=0$ , and:

$\Phi=0$  at PNG coast,  $\Phi=1$  at Solomons coast.

Consider velocity parallel to  $\Phi$  contours “equatorward”

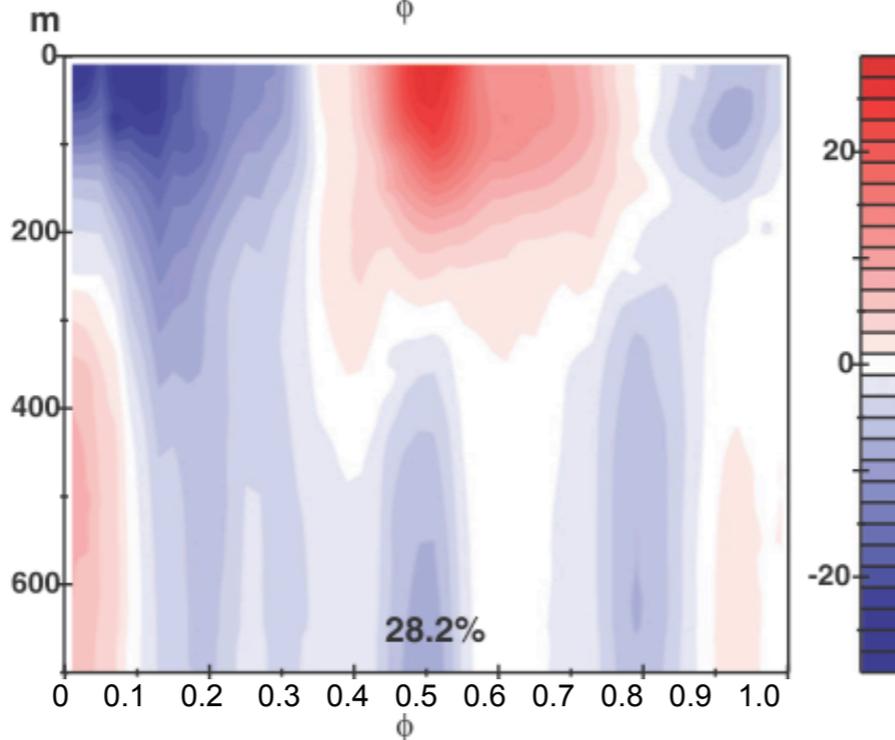

Mean  
eq-ward  
 $U_\phi$

NGCU core

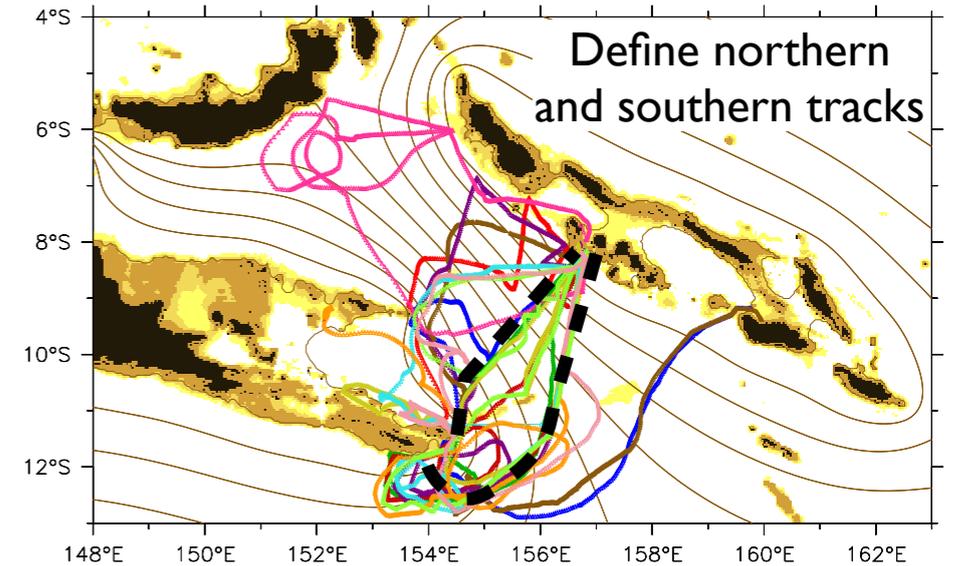

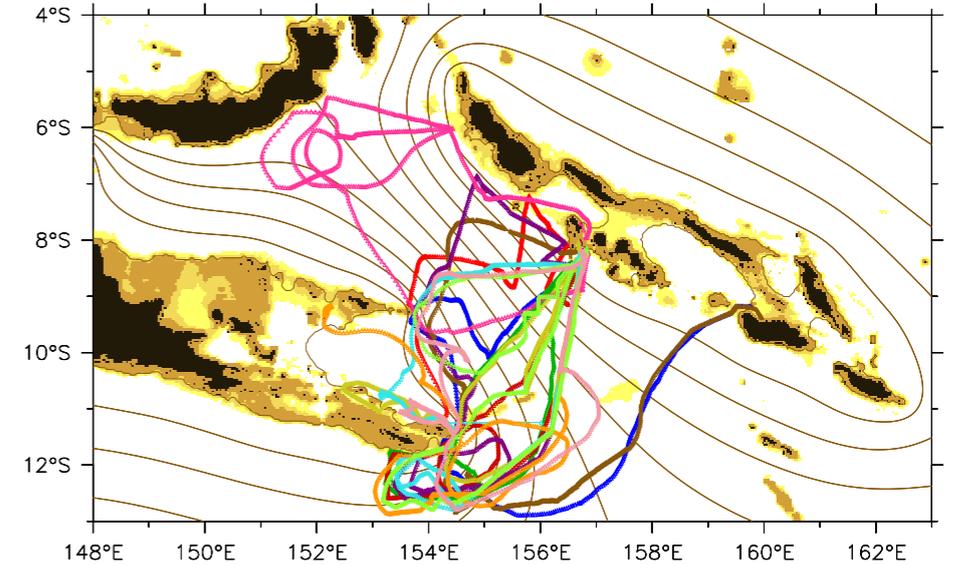

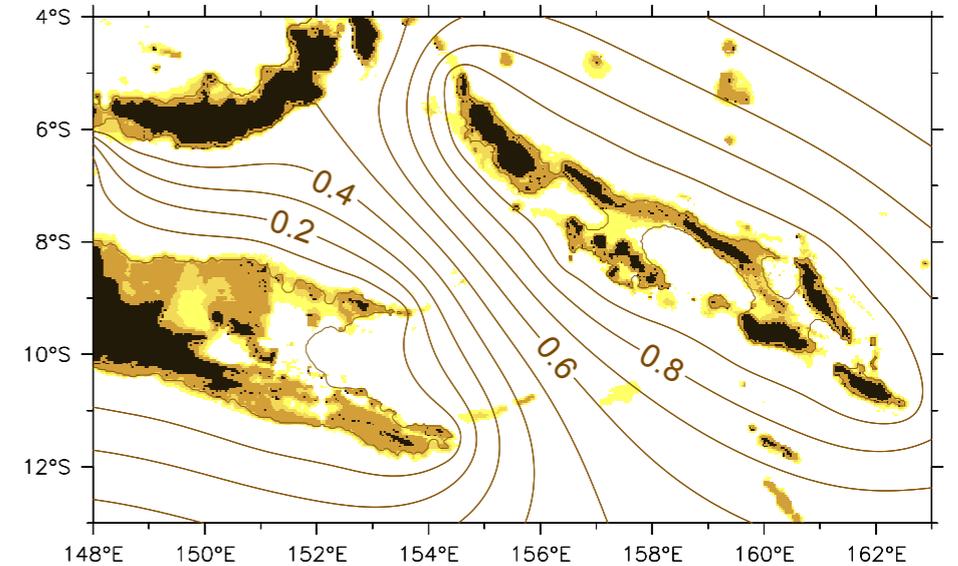

EOF 1

Variability is  
surface-intensified,  
dominantly ENSO

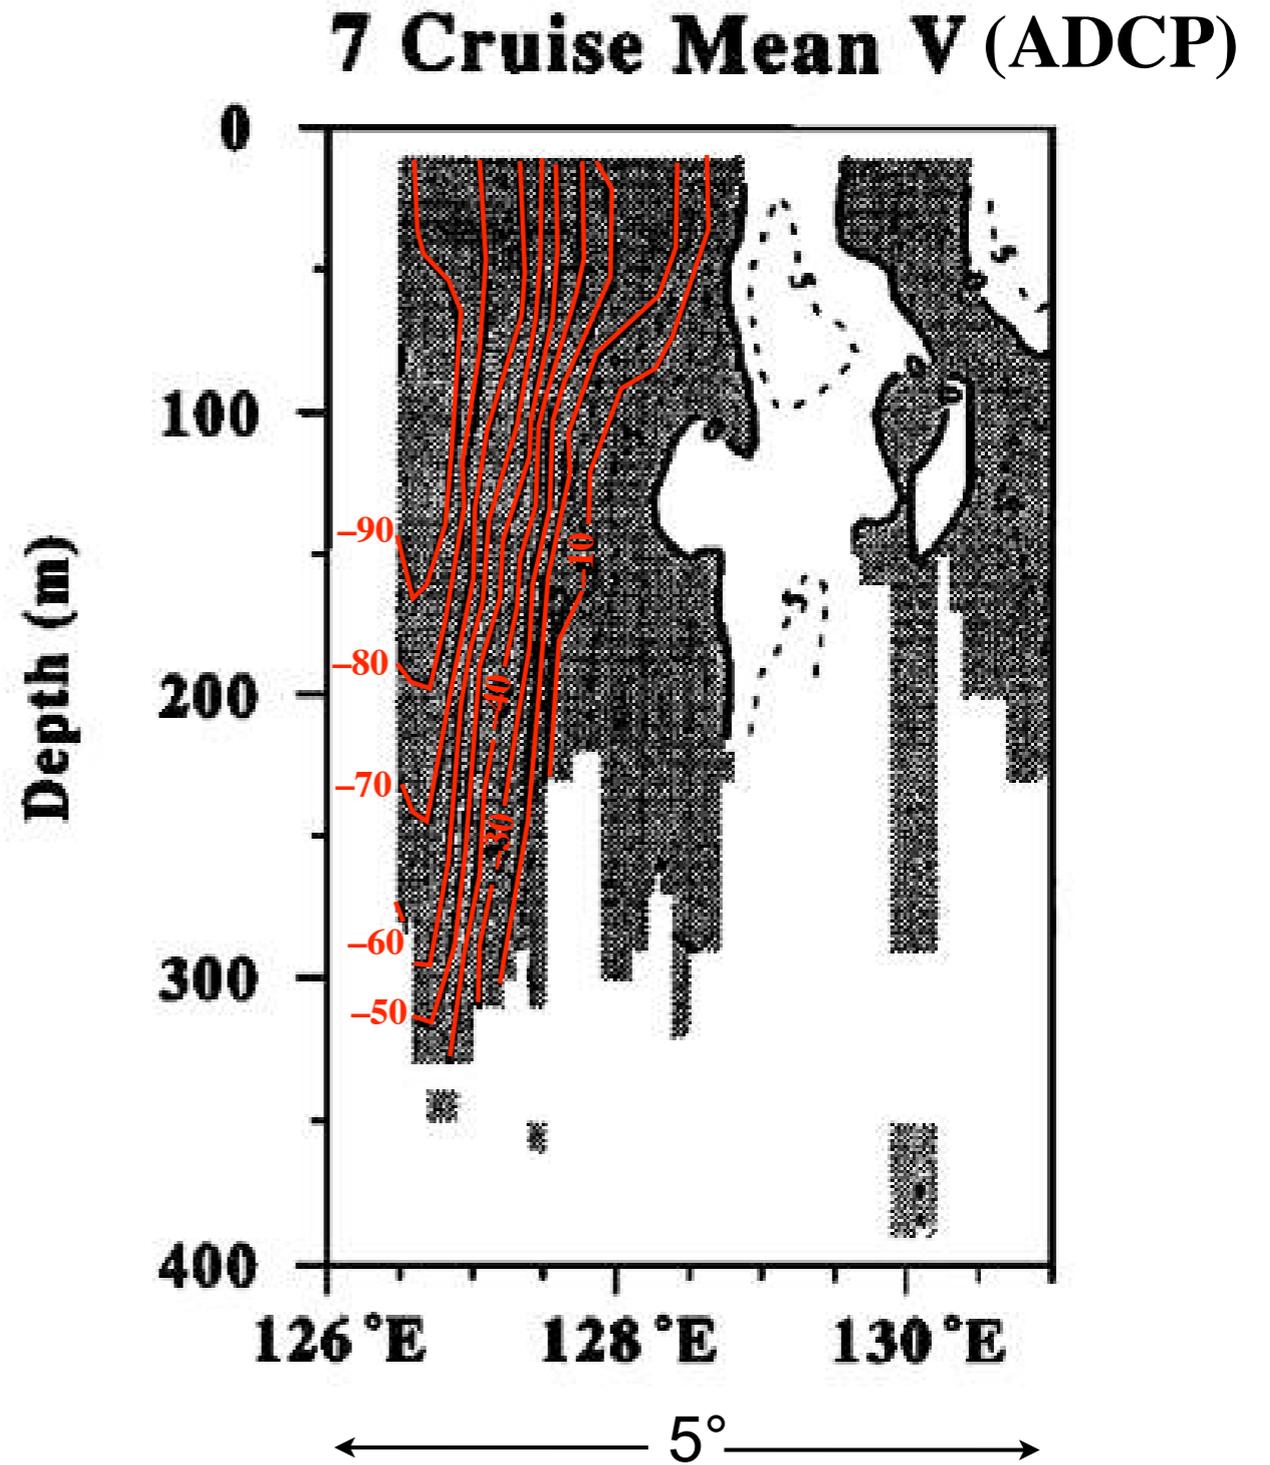

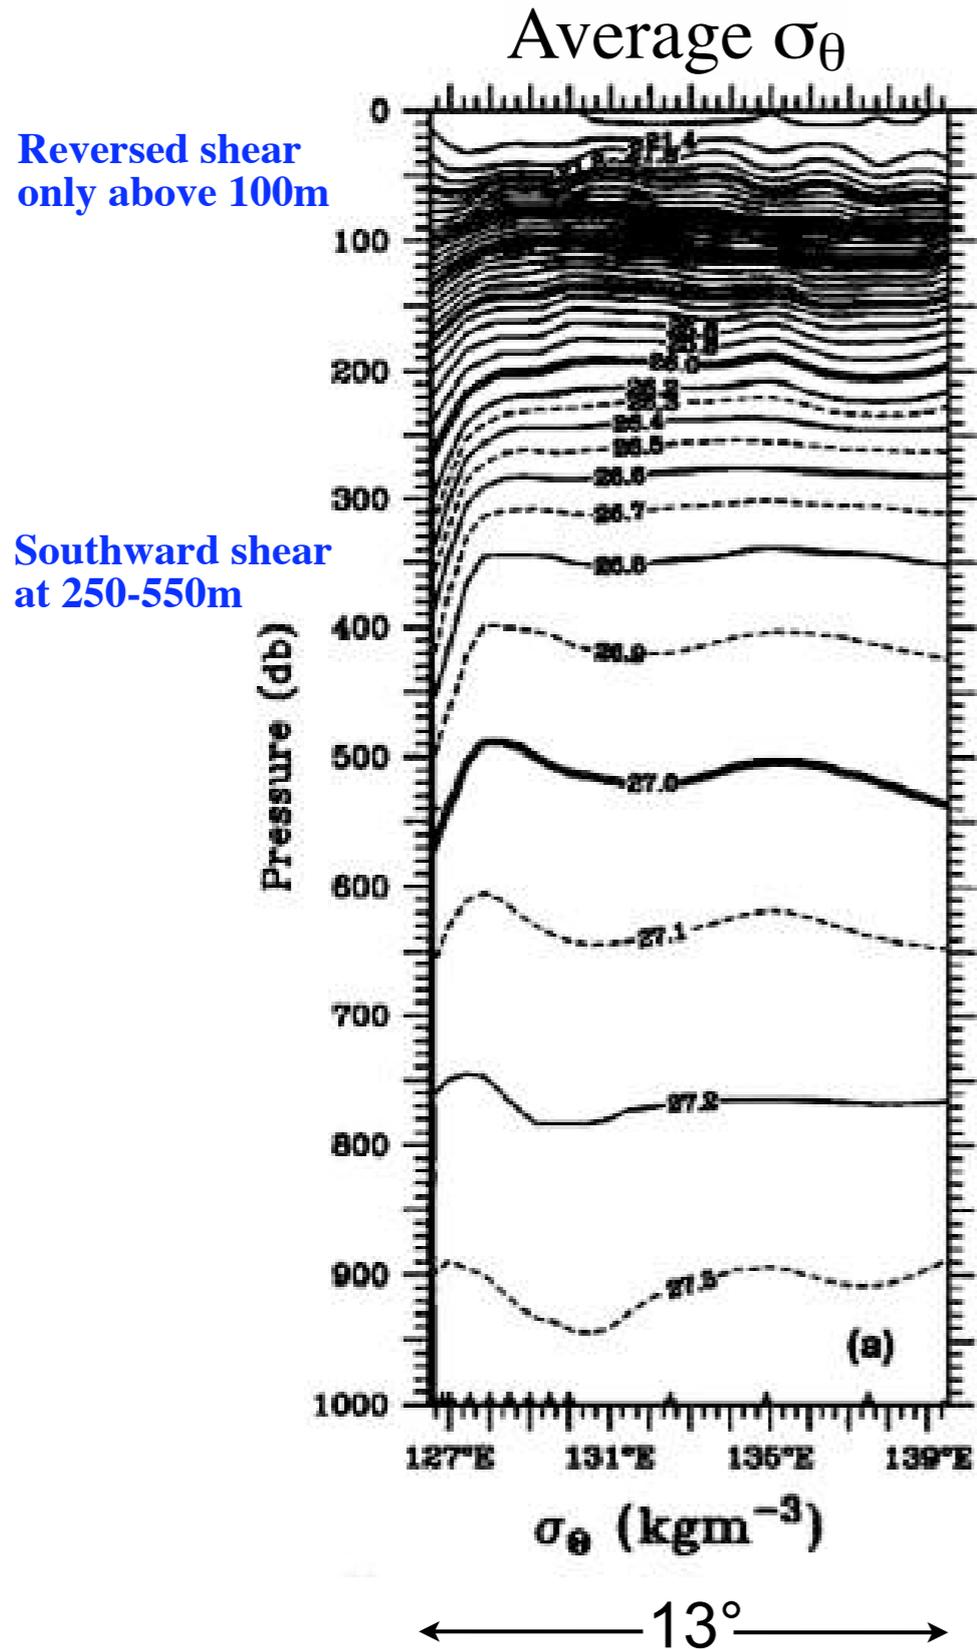

Contours of  $\Phi$  (by 0.1)

By contrast,

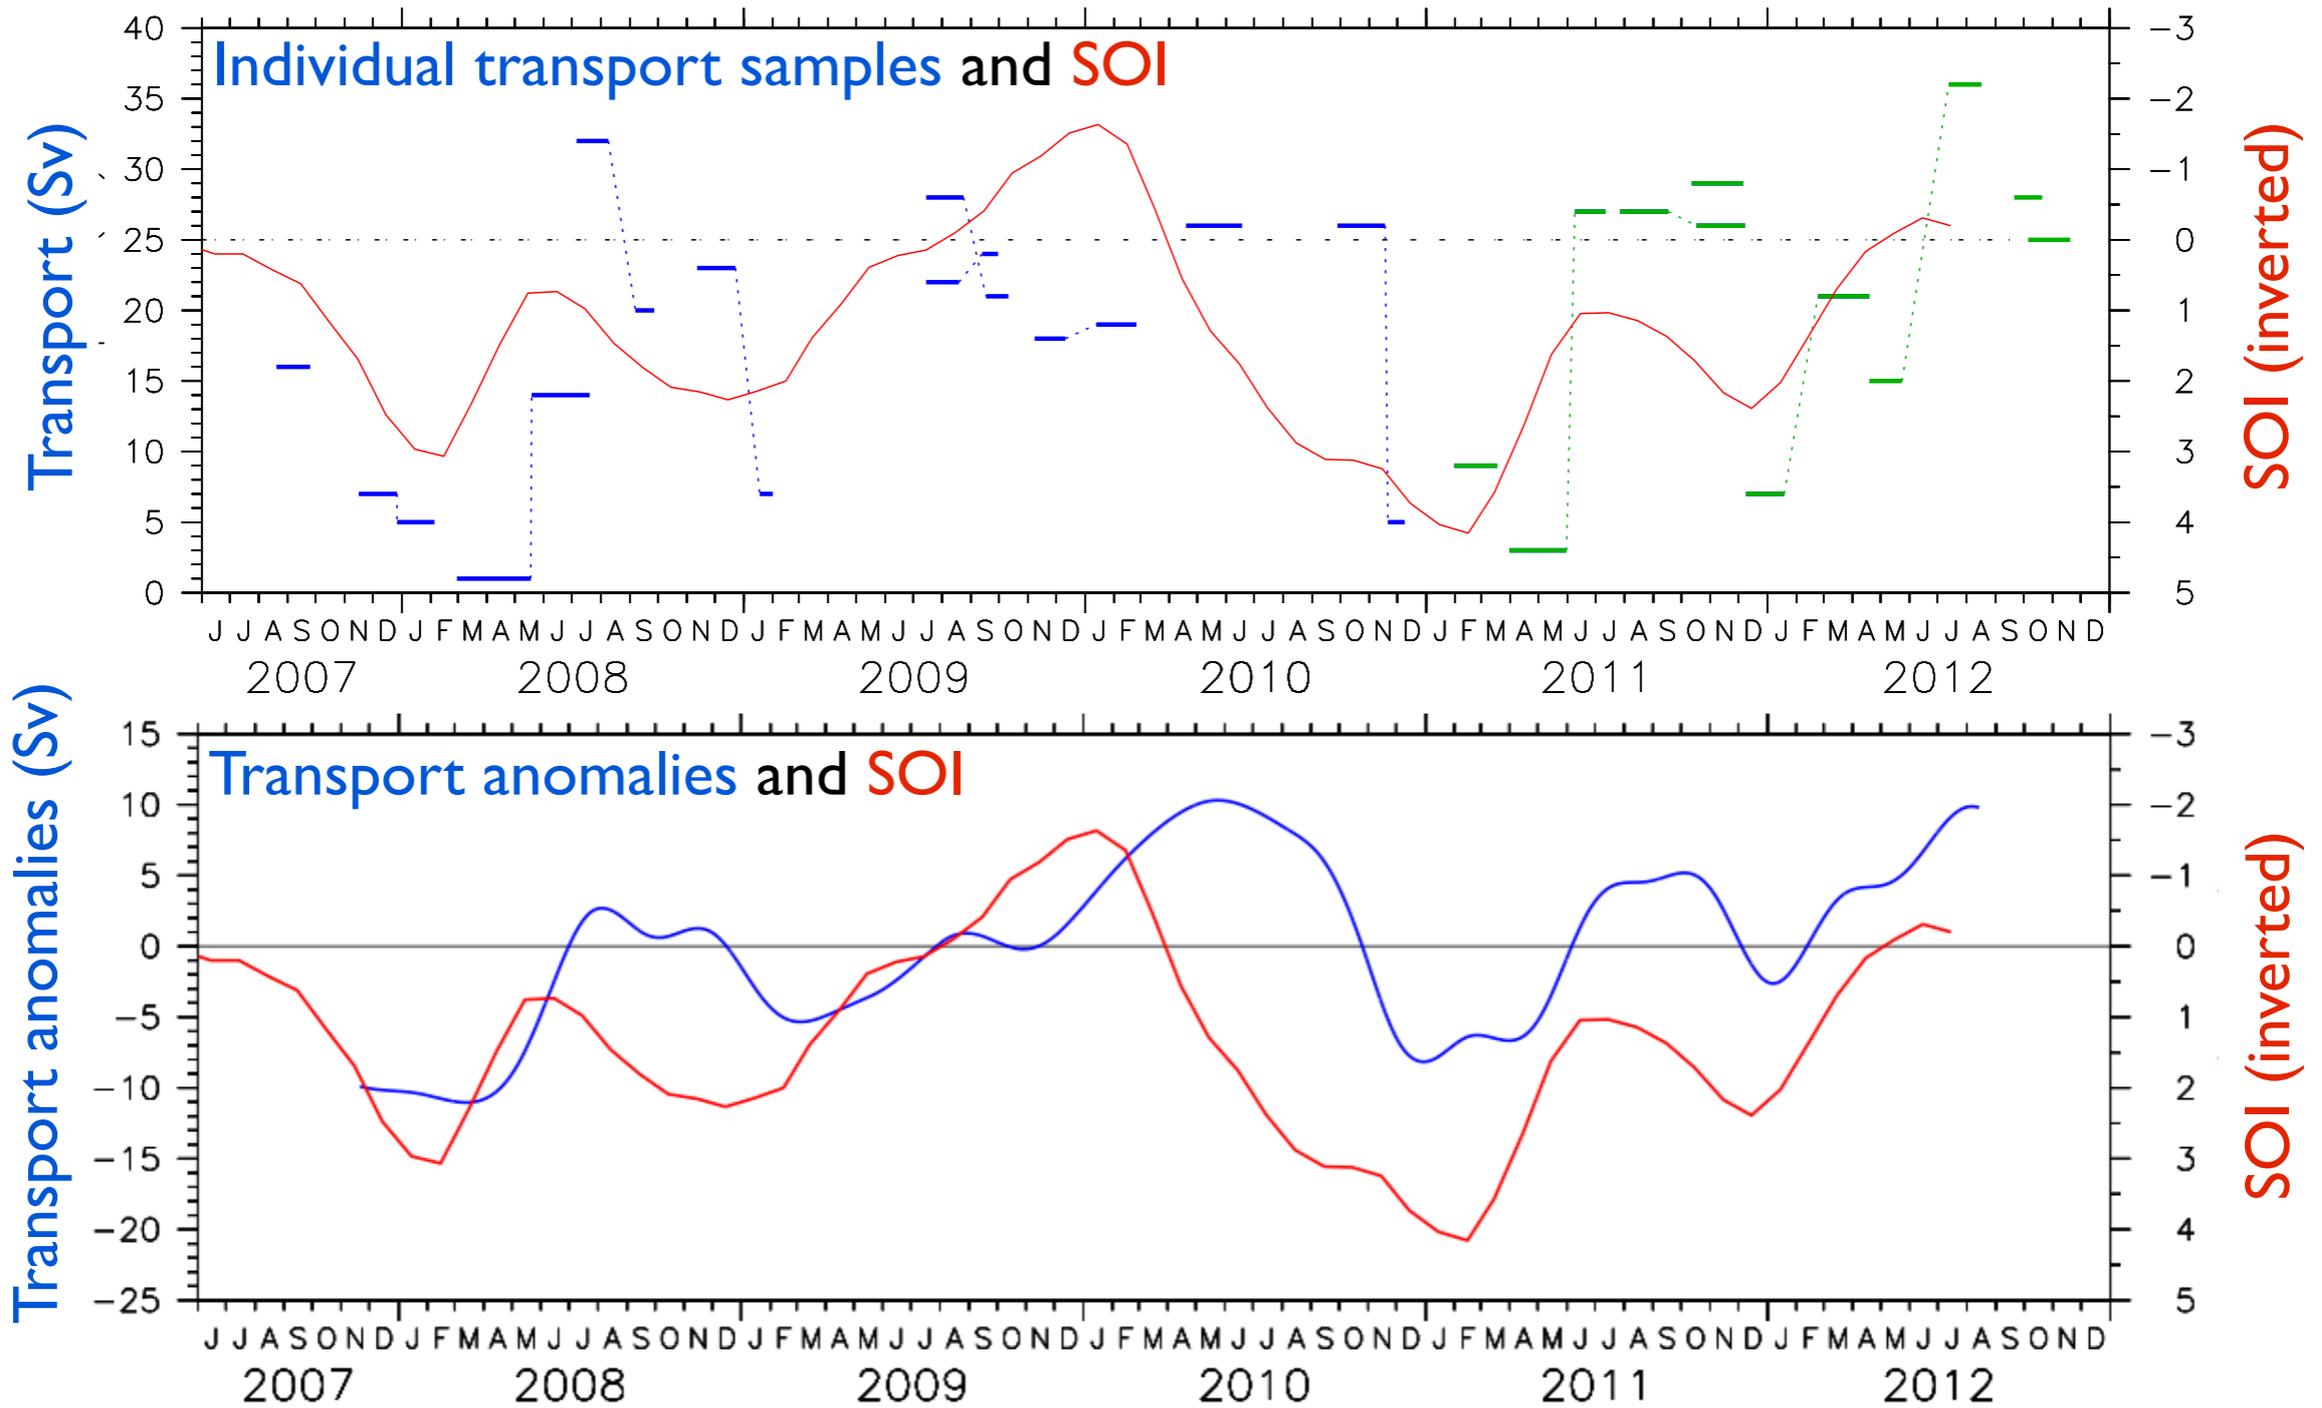

the Mindanao Current is surface-trapped, and shallow

Wijffels, Firing and Toole (1995)

# Solomon Sea transport has a strong ENSO cycle

Lags SOI by “a few months”

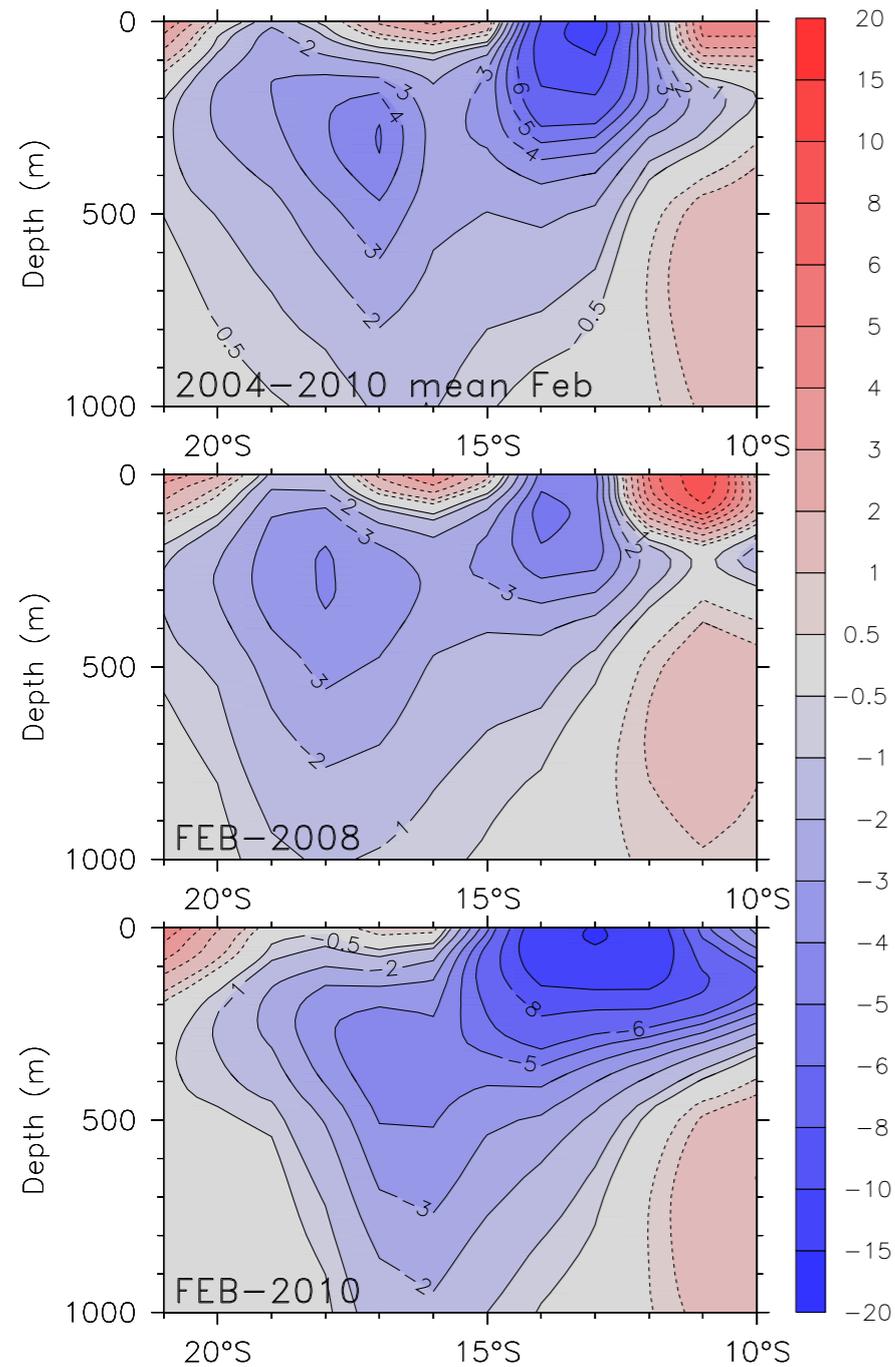

(Also high correlation between glider transport anomalies and AVISO velocity)

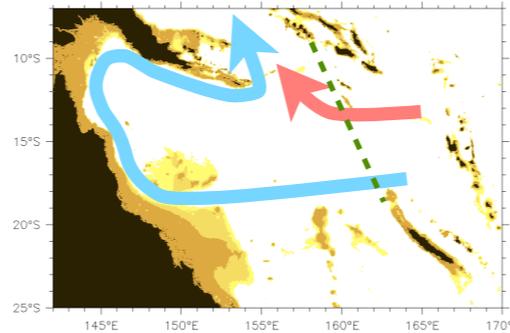

# ENSO variation of SEC at $\sim 160^\circ\text{E}$ is surface-intensified

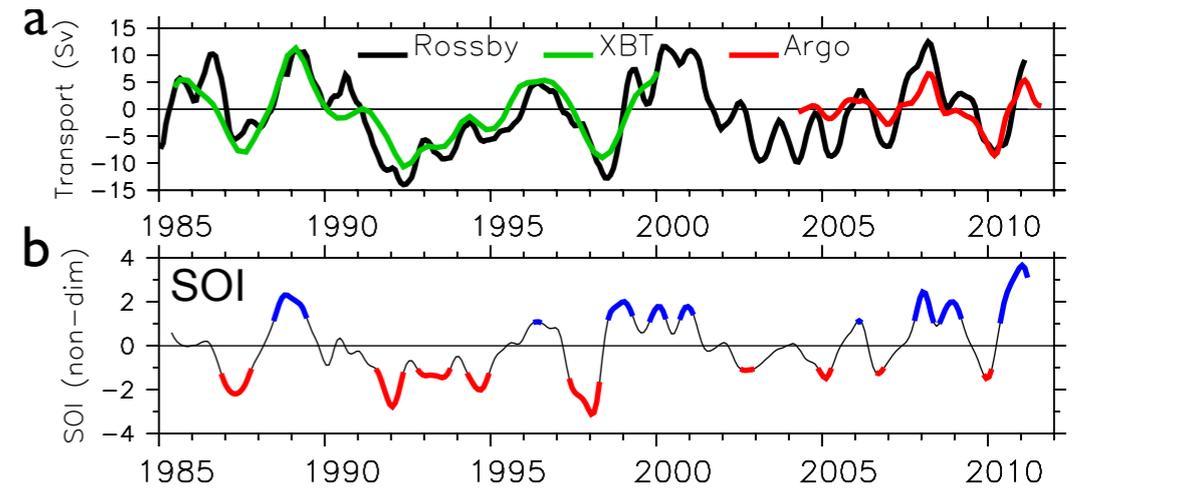

Examples of ENSO signal ( $U_g$  at  $160^\circ\text{E}$ )

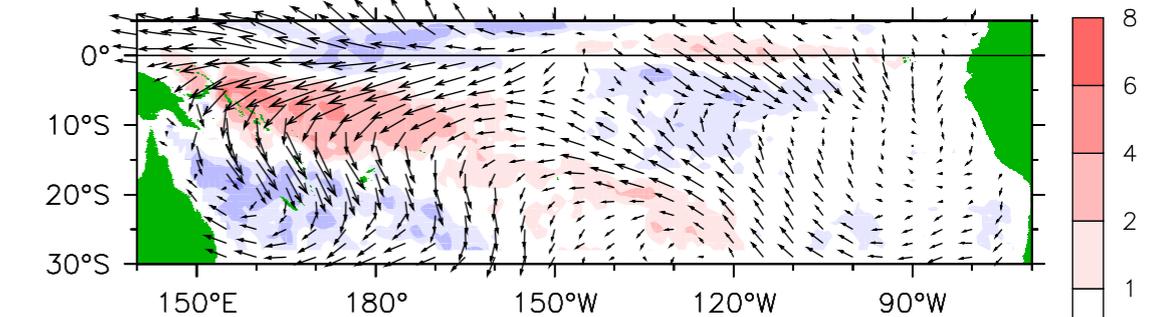

1.5-layer Rossby model gives much of the transport

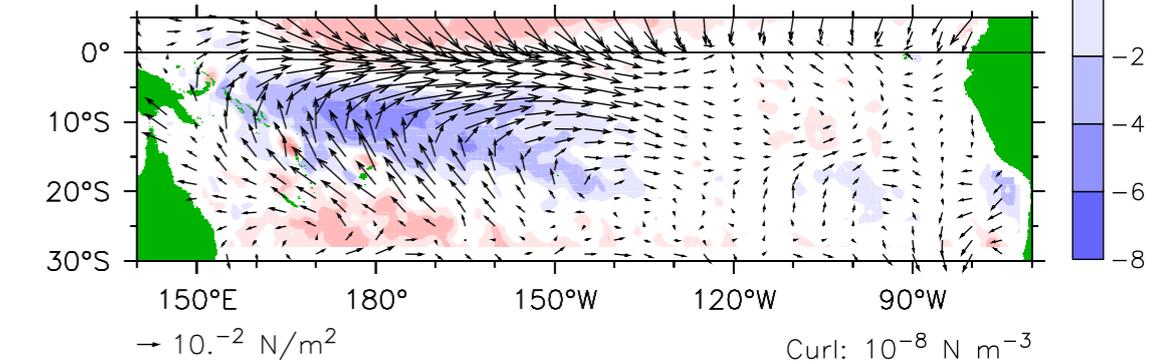

XBT line (green) and schematic circ.

c. La Niña

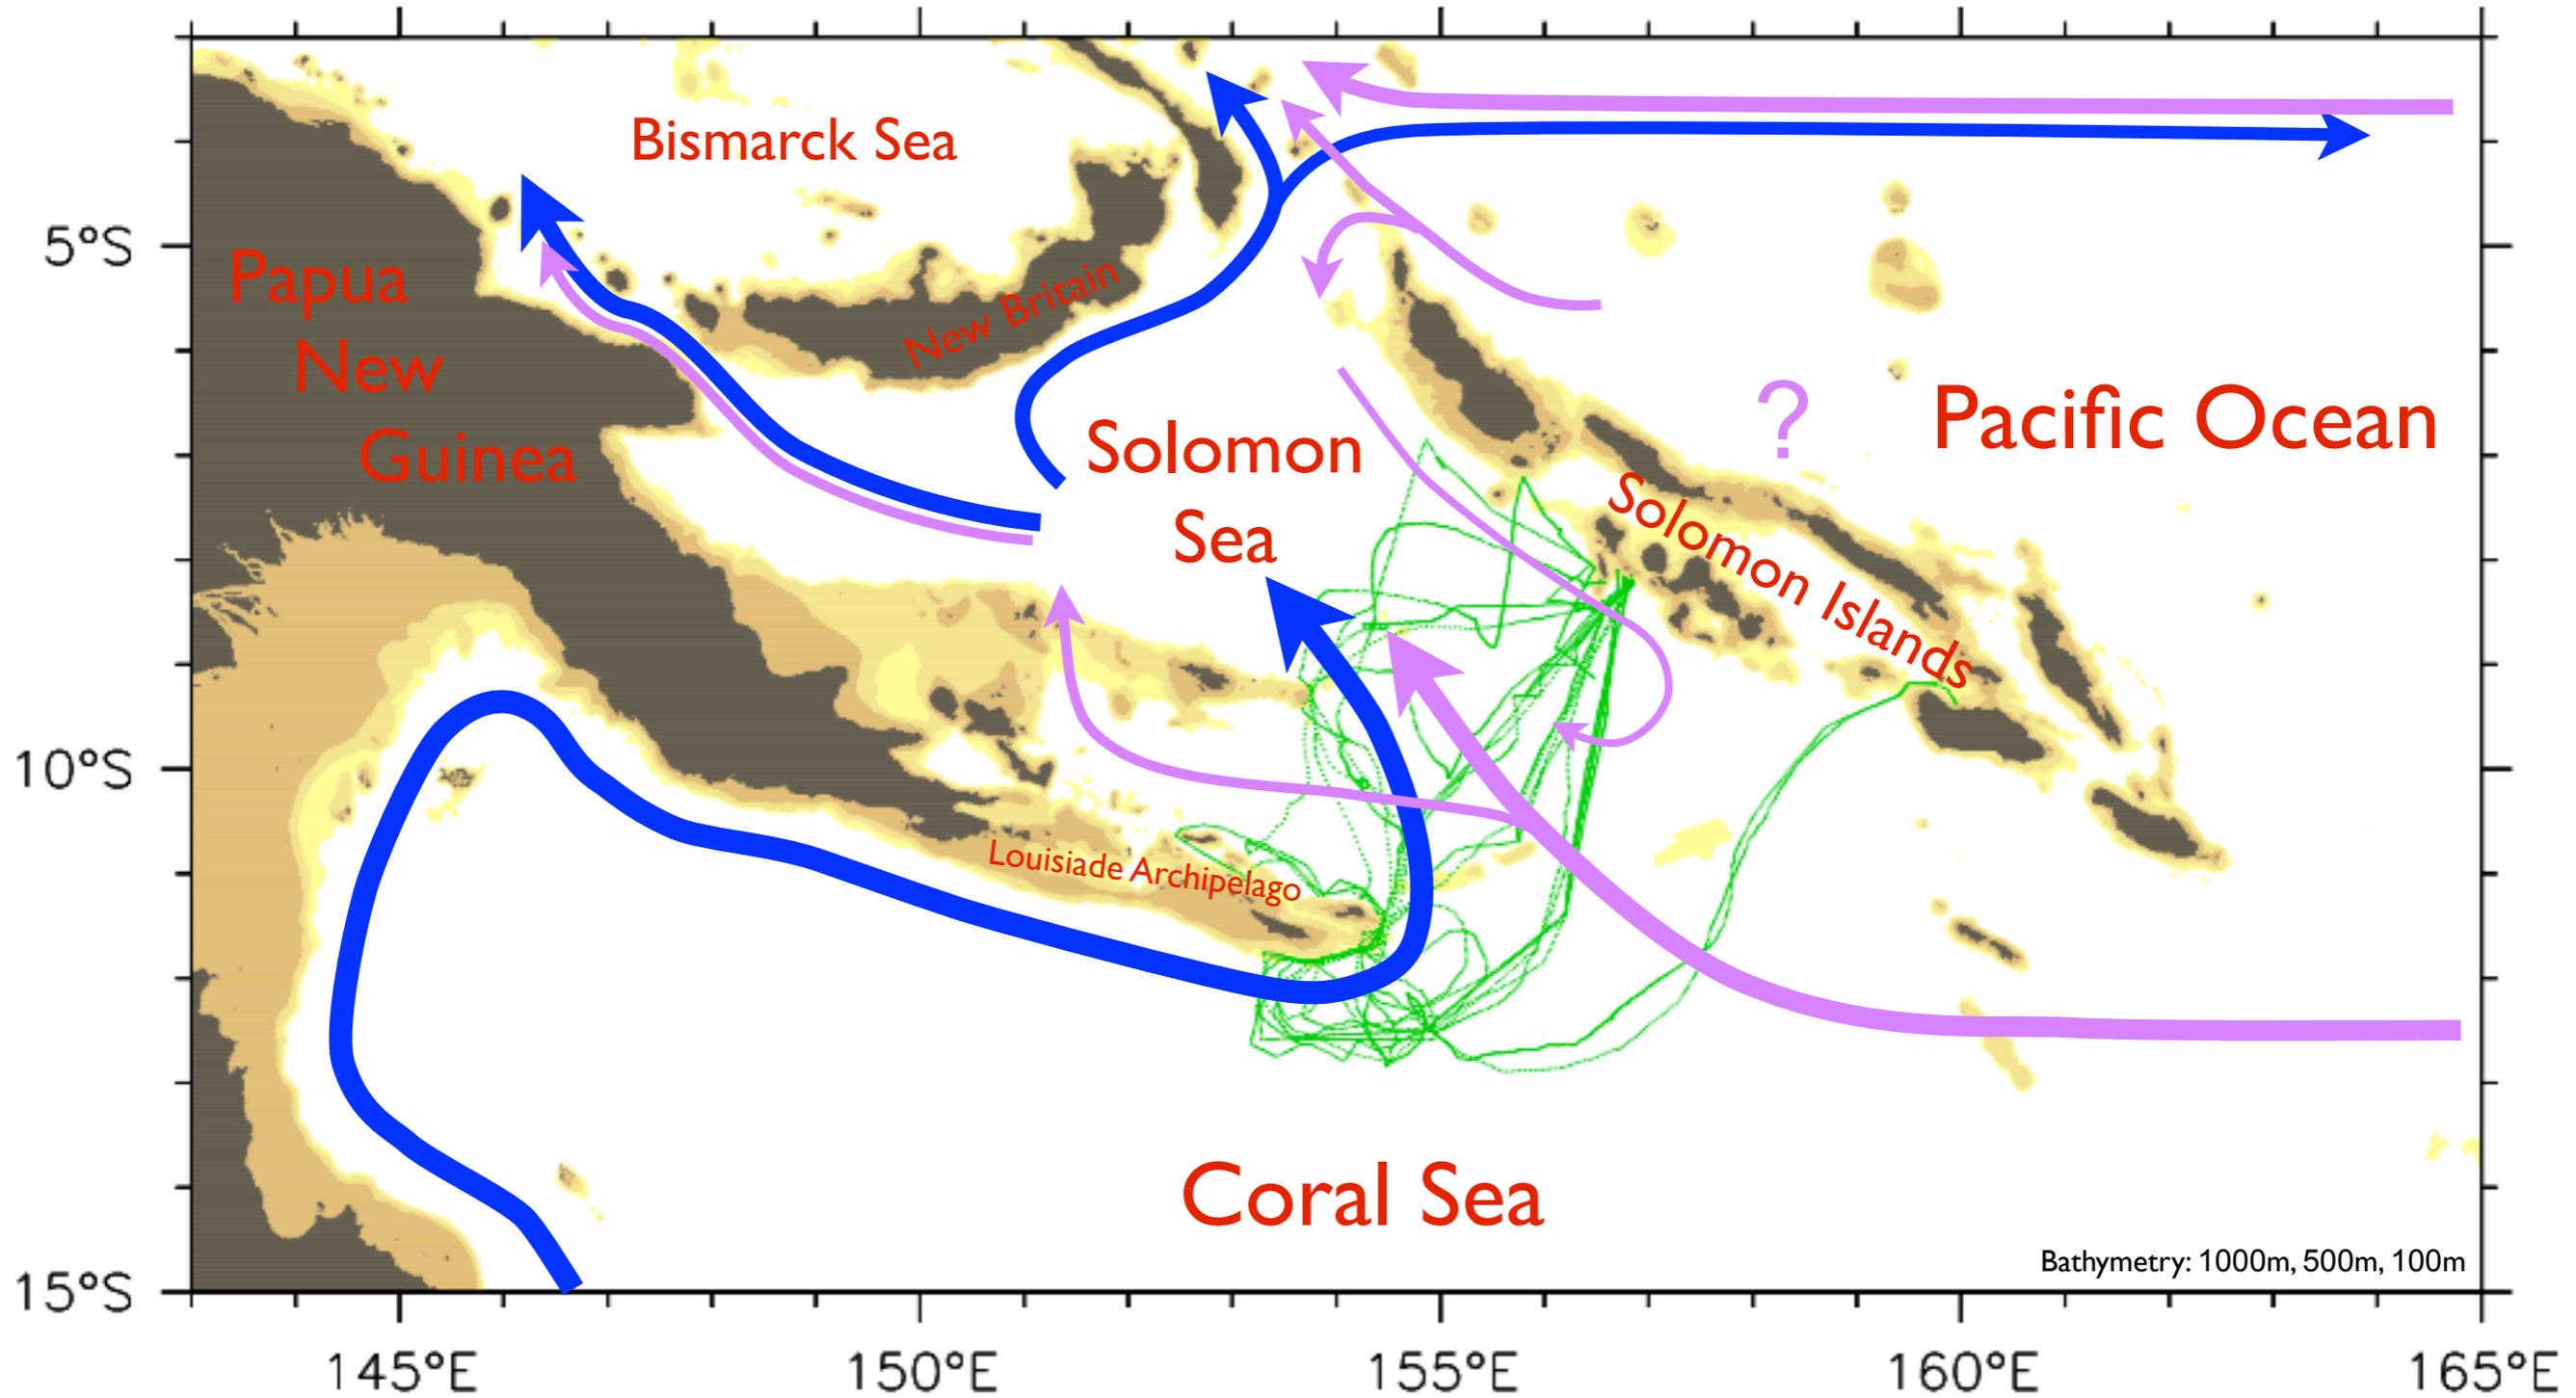

d. El Niño

# What are the sources of the two Solomon Sea inputs?

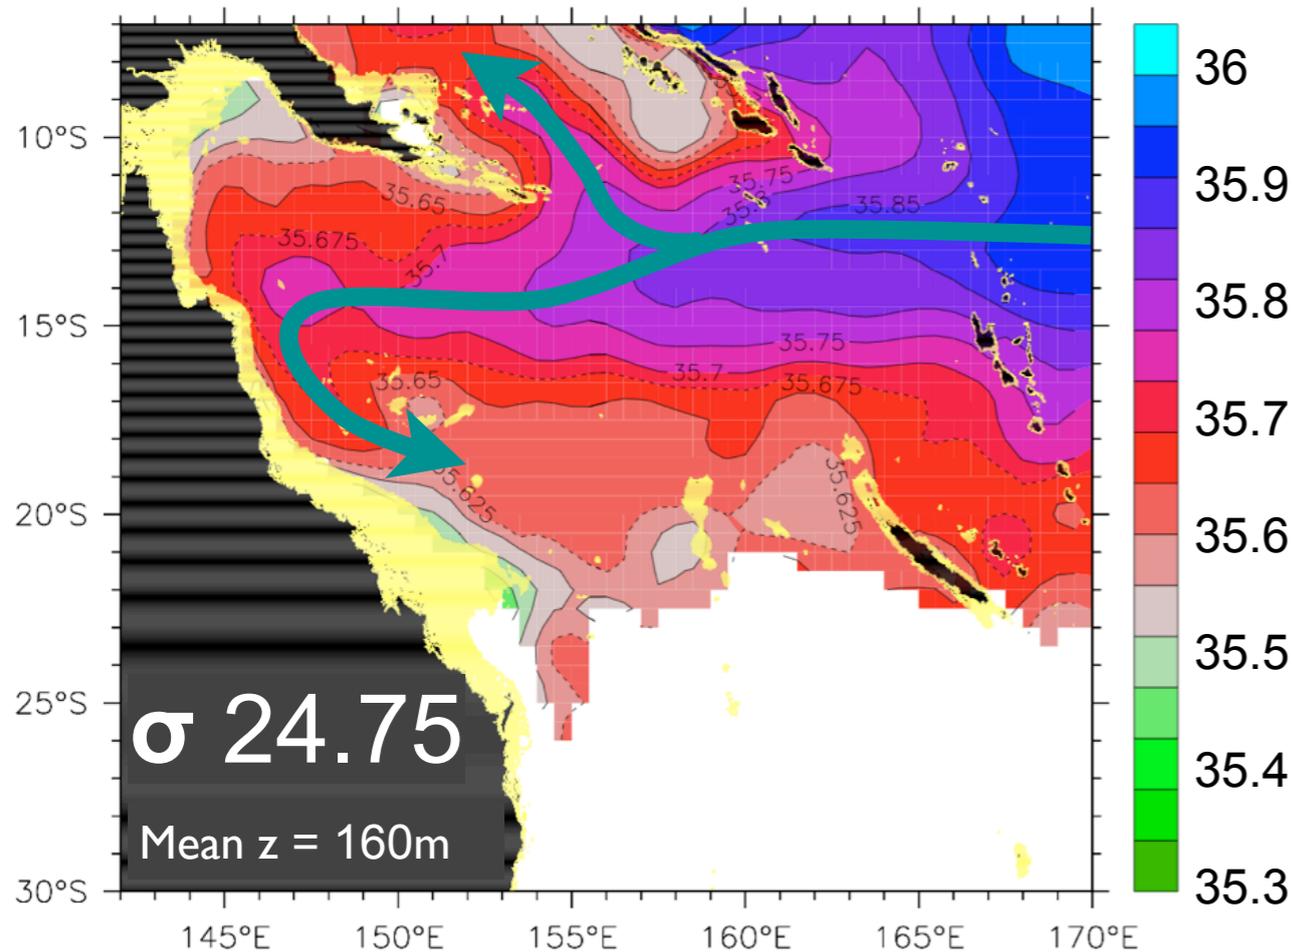

Highly schematic circulation

Upper layer  
Subthermocline

# Two distinct high-salinity tongues

At the level of the subtropical high-S max  
(NVJ)

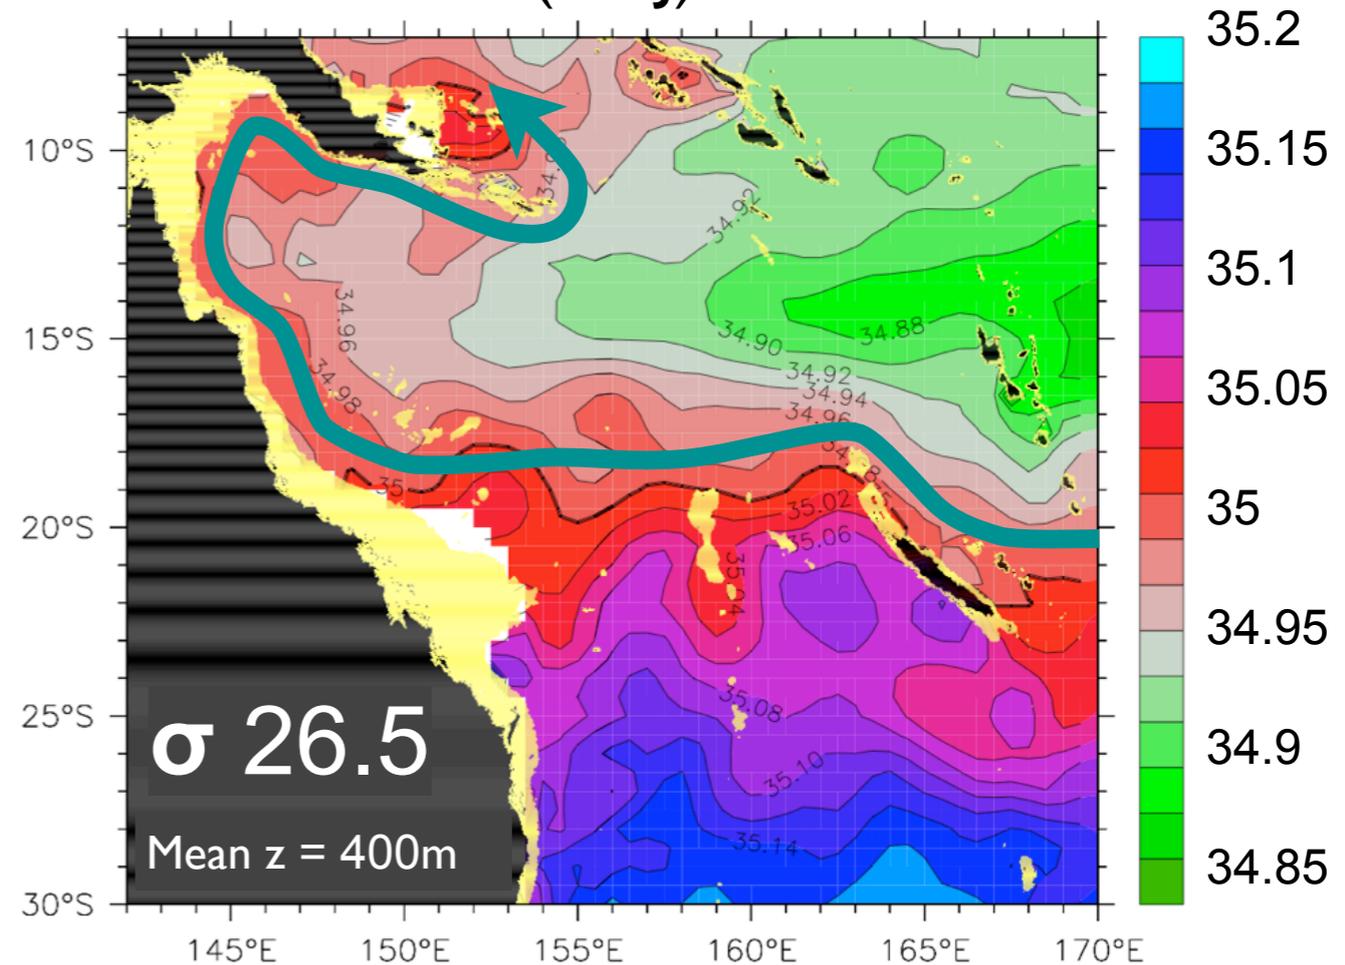

Subducted in the eastern subtropics  
(~ 20°S, 120°W)

Enters the Coral Sea north of Vanuatu

Splits, flowing:

- directly into the Solomon Sea, and
- south into the EAC.

At the base of the thermocline  
(NCJ)

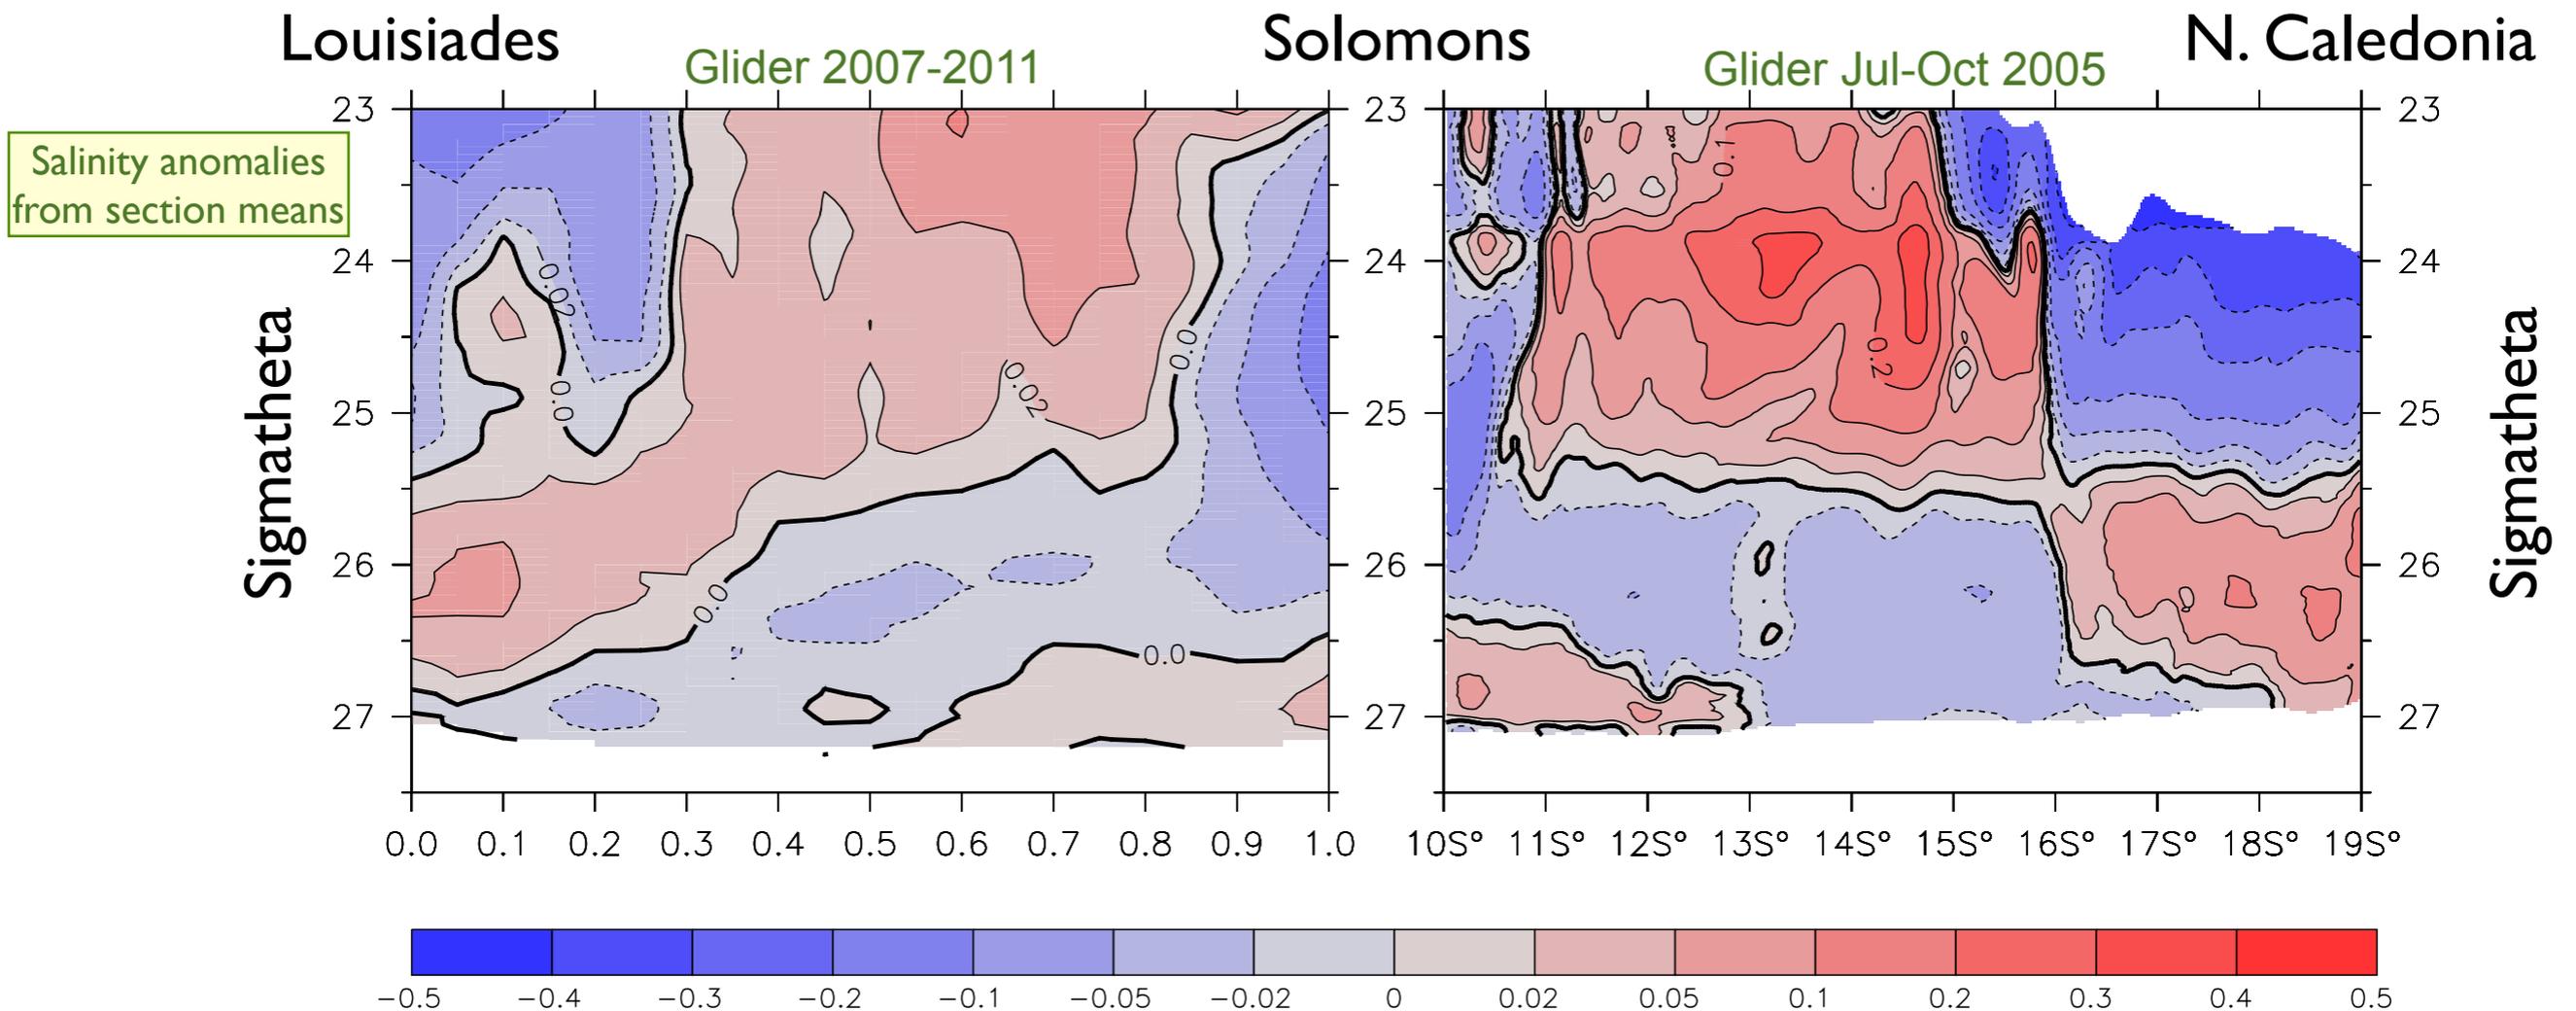

Subducted in the Tasman Front  
(~ 35°S, 160°W)

Enters the Coral Sea in the N. Caledonian Jet

Flows as a western boundary current

- along the Queensland and PNG coasts
- into the Solomon Sea.

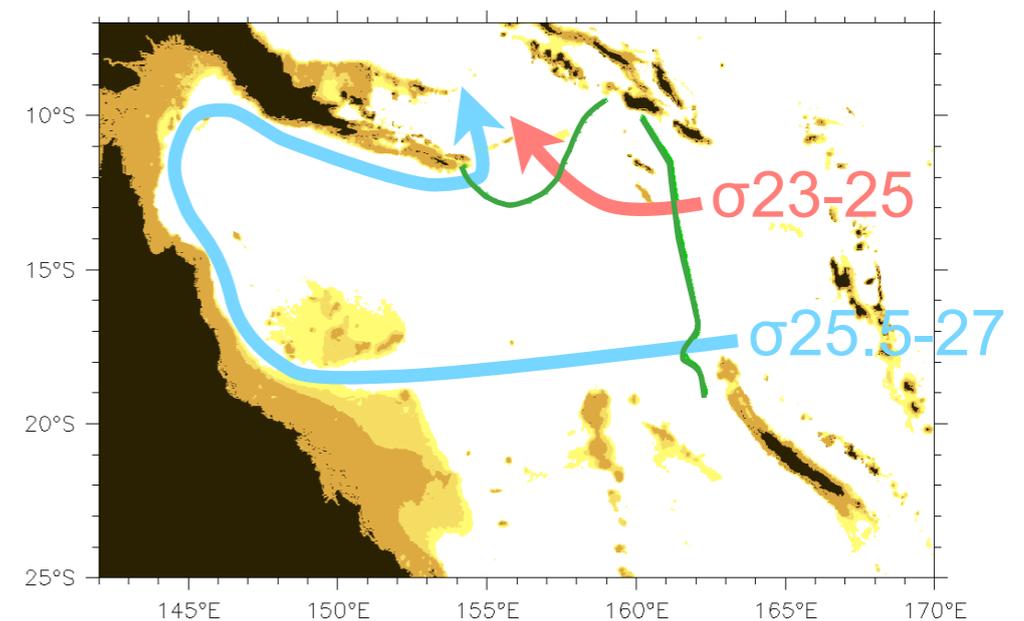

# Salinity anomalies on isopycnals: 2 glider sections from the Solomons

Glider sections from the Solomons to:

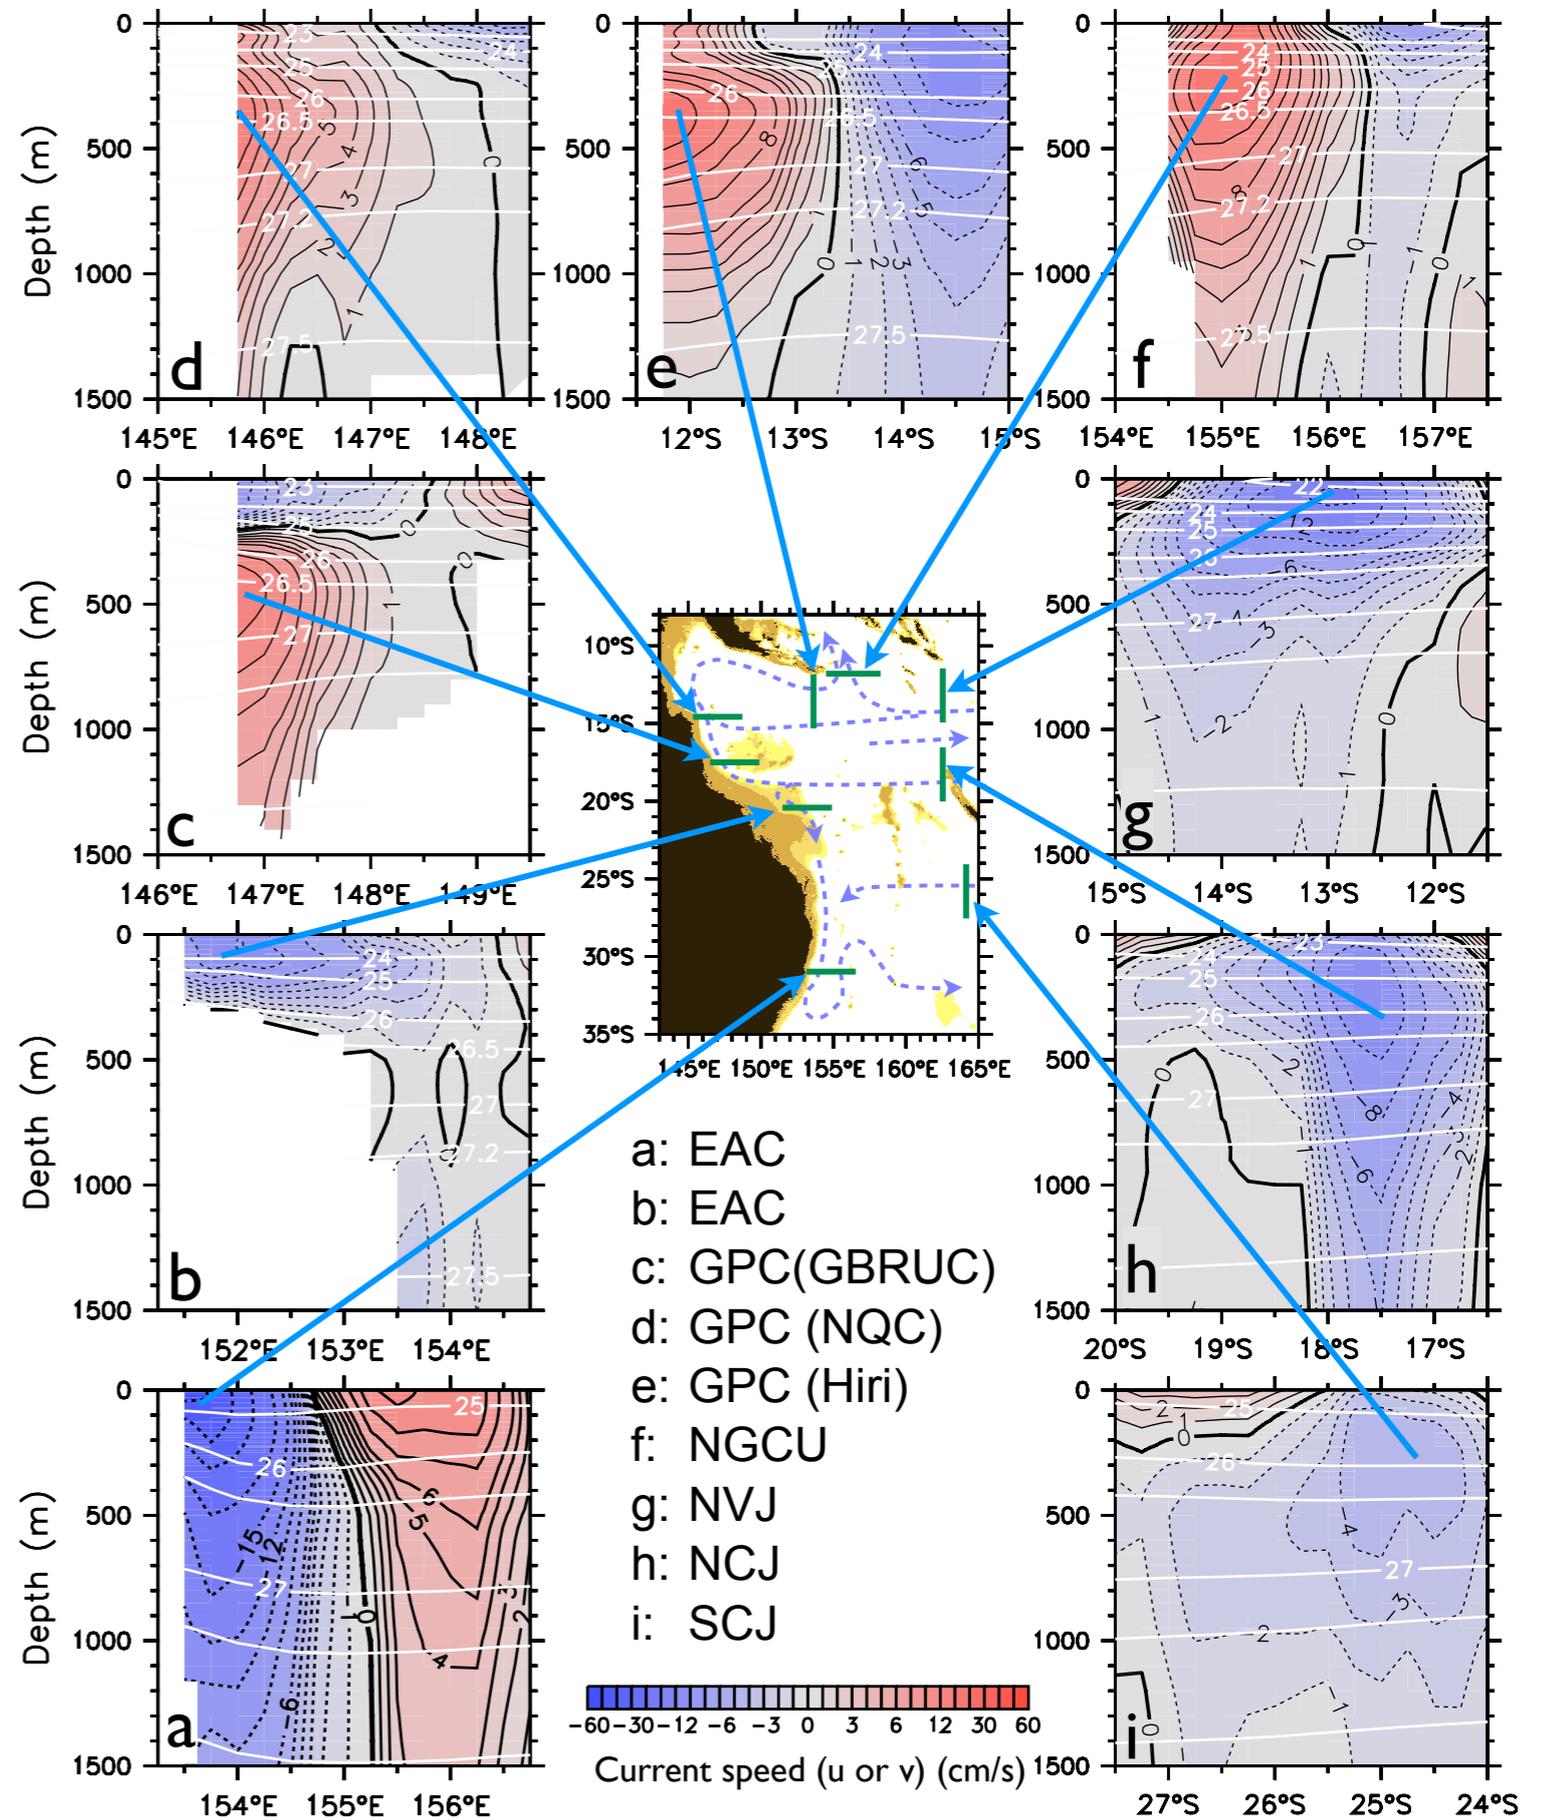

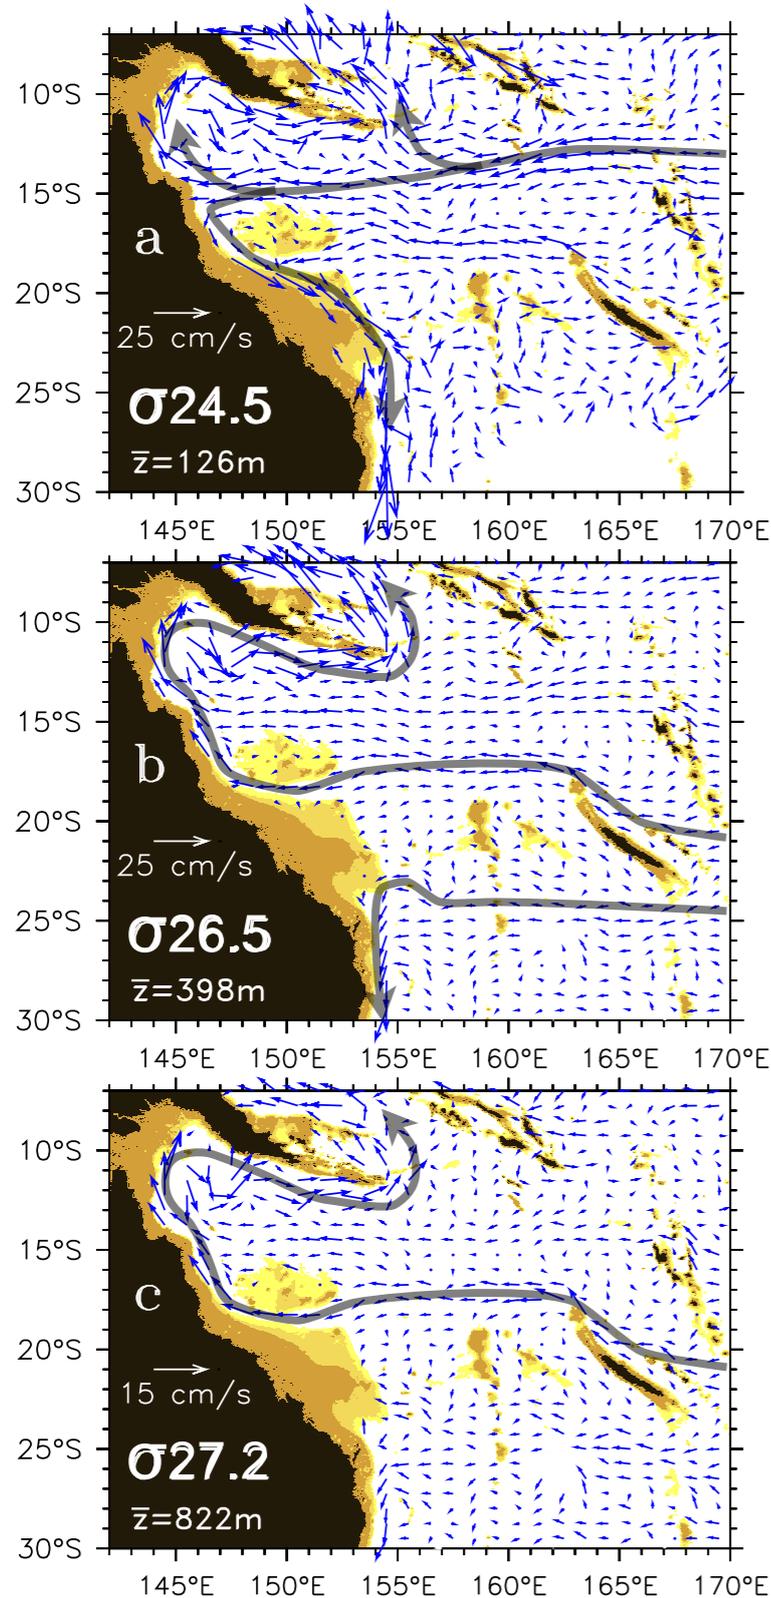

- New Caledonia (Jul-Oct 2005)
- Louisiades (15 sections, 2007-ongoing)  
(green lines at right)

High-S tongues carried across and around the Coral Sea at shallow and mid-depth isopycnals

# Absolute geostrophic currents

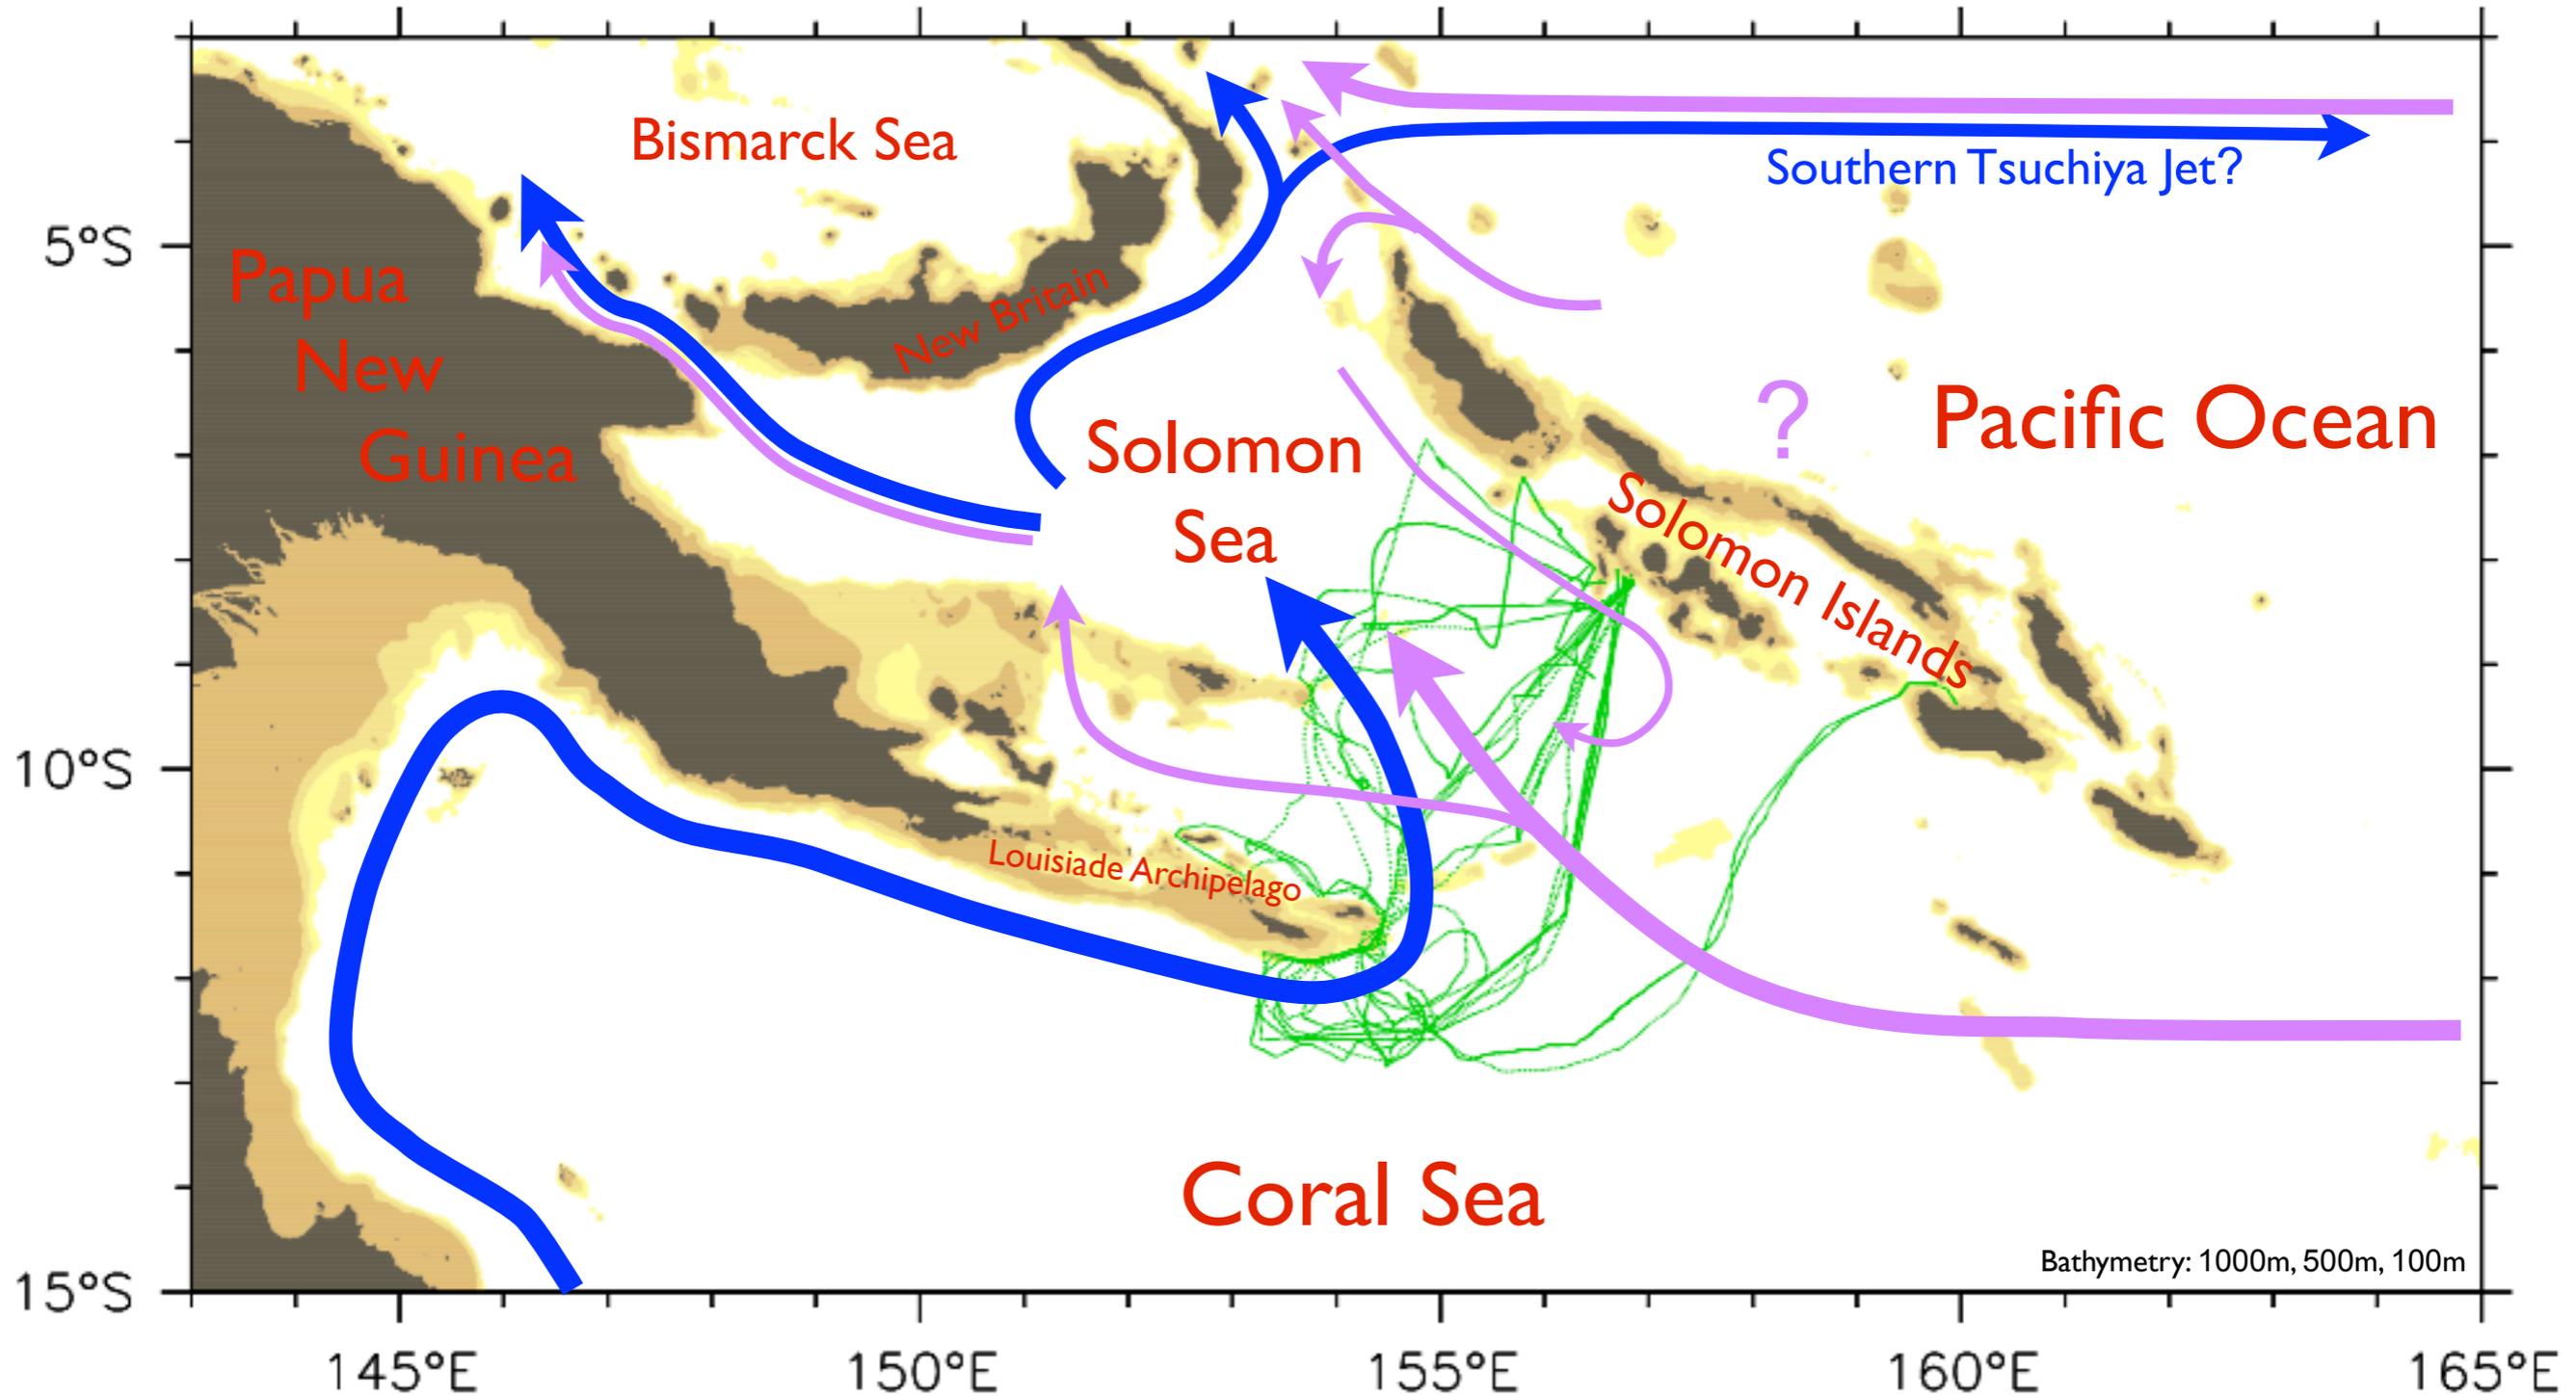

CARS  $u_g$  referenced with Argo trajectory motion (more later)

If NGCU is subthermocline, and (relatively) invariant at ENSO timescales, where does that water go?

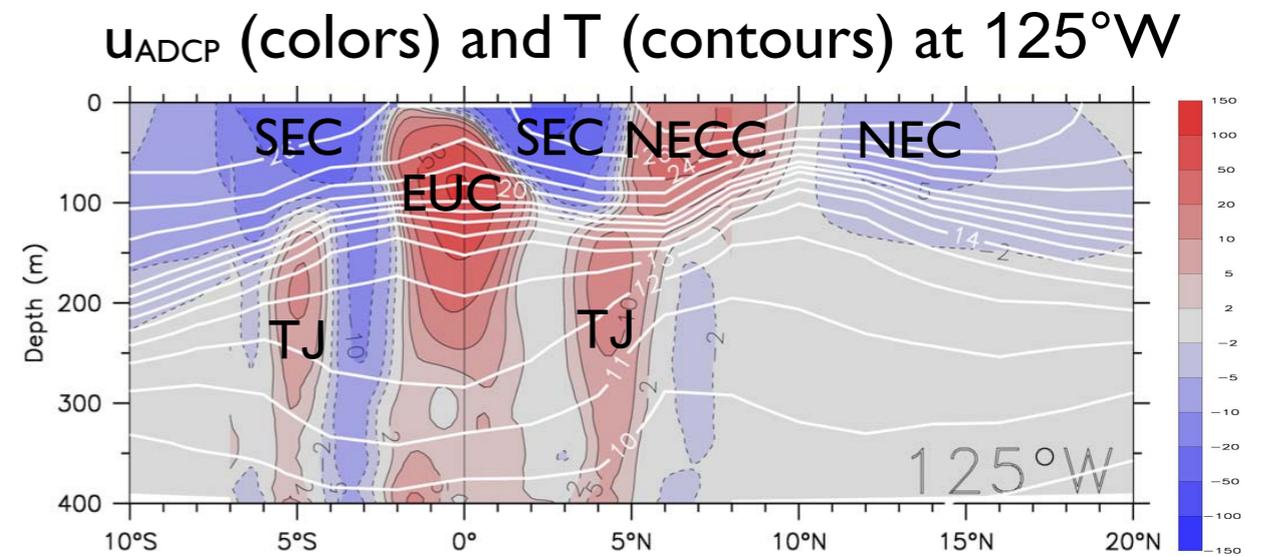

Highly schematic circulation

Upper layer  
Subthermocline

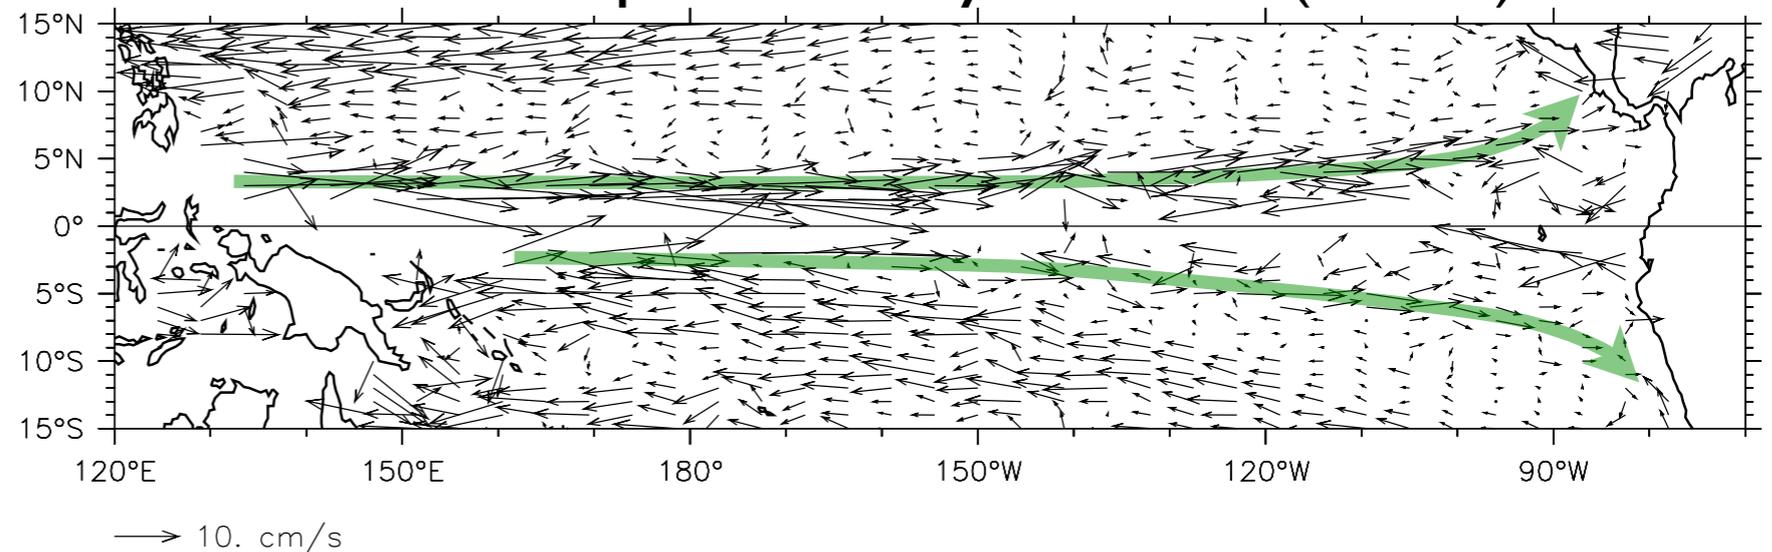

# Tsuchiya Jets overview

Tsuchiya Jets flow across the entire Pacific at about 13°C (2-300m), feeding upwelling in the Costa Rica Dome and Peru coast.

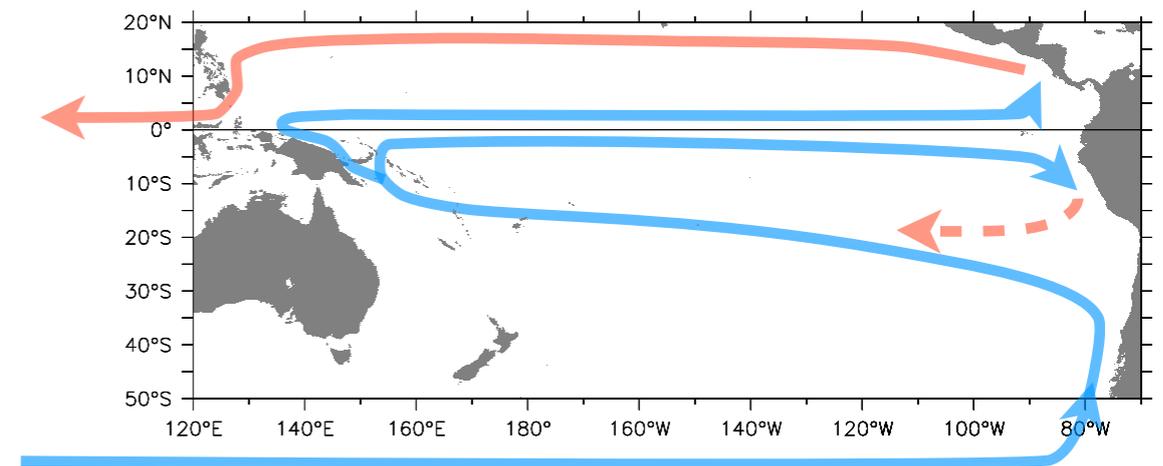

## Geostrophic velocity at 200m (CARS)

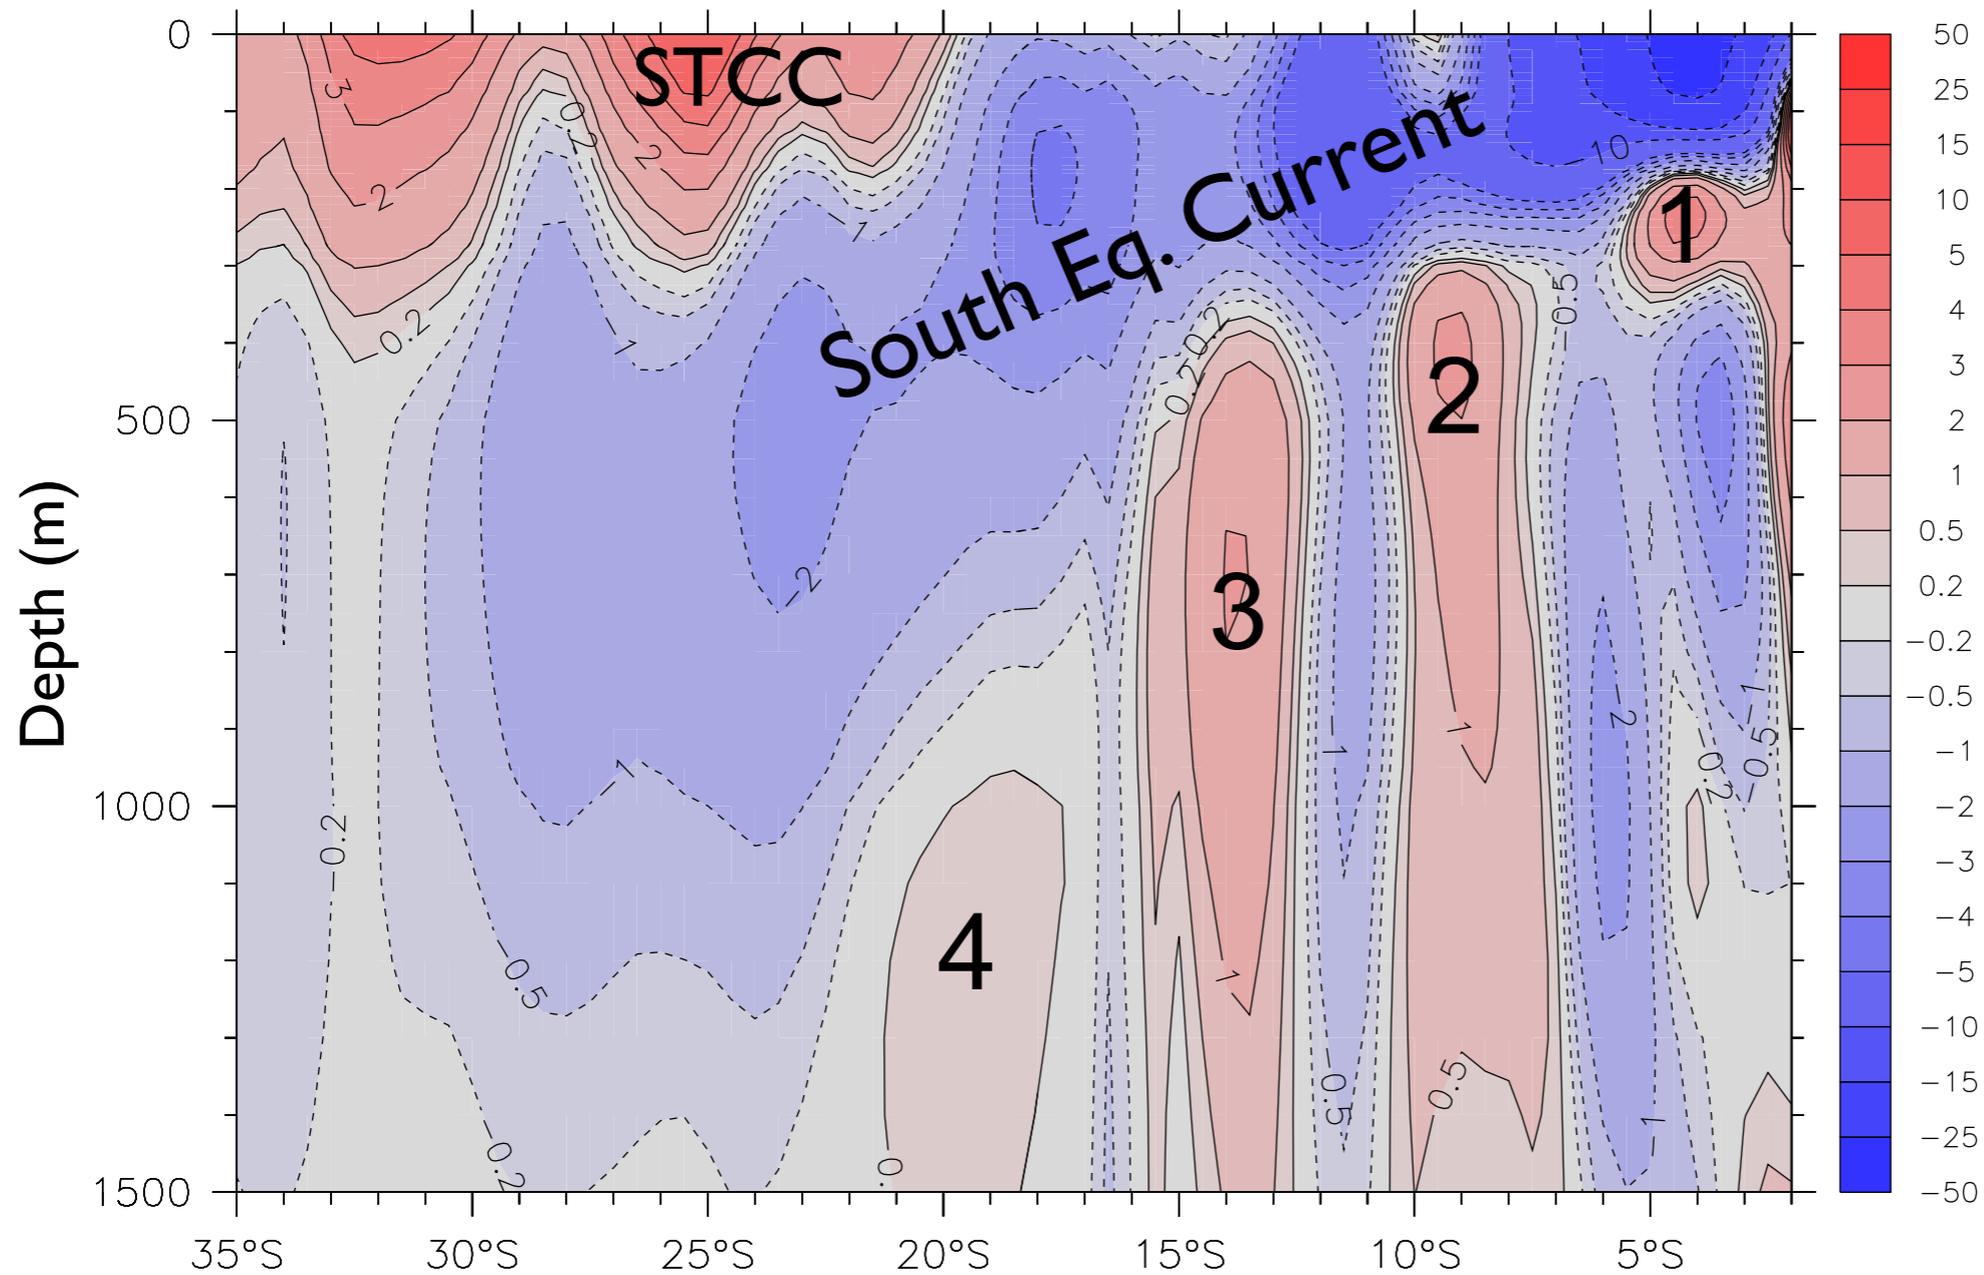

Water entering the South Pacific must  
 (a) be lifted through the thermocline, and  
 (b) cross the equator  
 Equatorial upwelling is shallow (next slide),  
 but CR Dome and Peru upwelling  
 reaches much deeper ( $\beta$ -plume).

Cold water enters in the southeast  
 Warm water leaves in the Indonesian Throughflow

# Secondary, tertiary, quaternary Tsuchiya Jets?

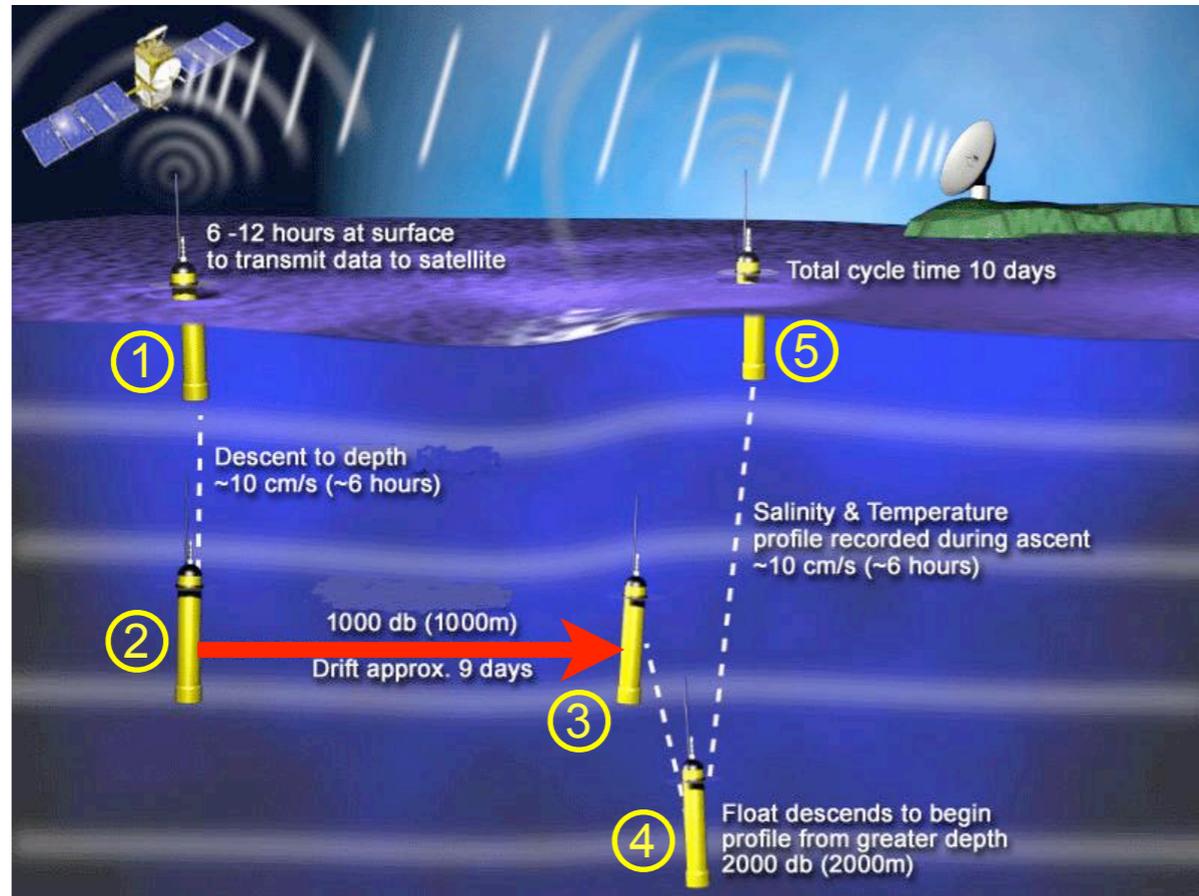

Mean  $u_g$  over 160°W-130°W (CARS)

Plausible if  
multiple sources  
of upwelling in  
the east ...  
how to observe?

# Treatment of Argo trajectory data

- 1 - Select all (892) Argo floats in the box 120°E-80°W, 12°S-12°N, from 1/2003 à 8/2011
- 2 - Calculate subsurface velocities from float motion (Park et al., 2005) ...

IF:

- Times of all 5 “events” are known ... and if ...
- Advection during ascent, descent and surface drift can be estimated (usually geostrophy + Ekman drift)

THEN:

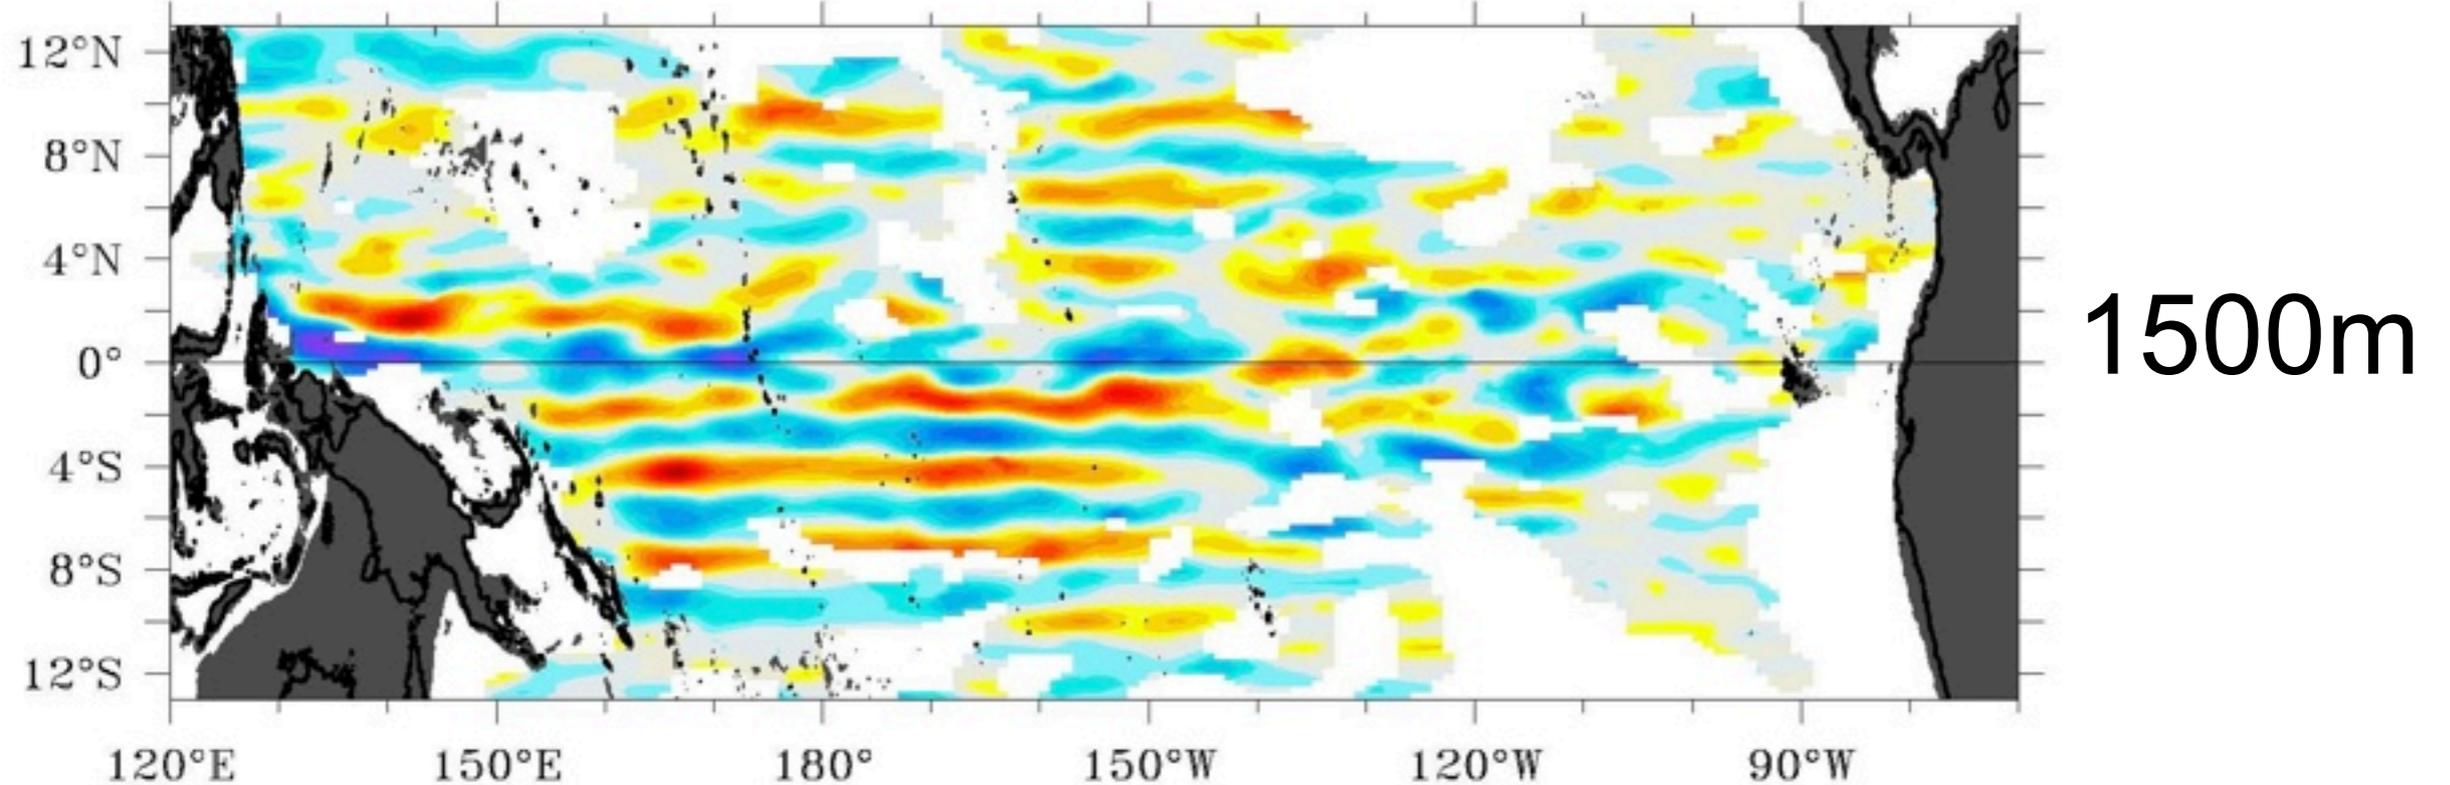

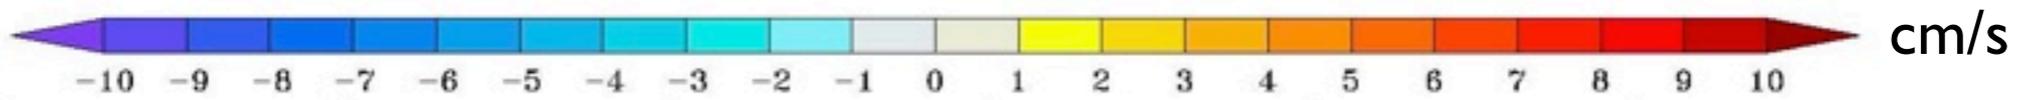

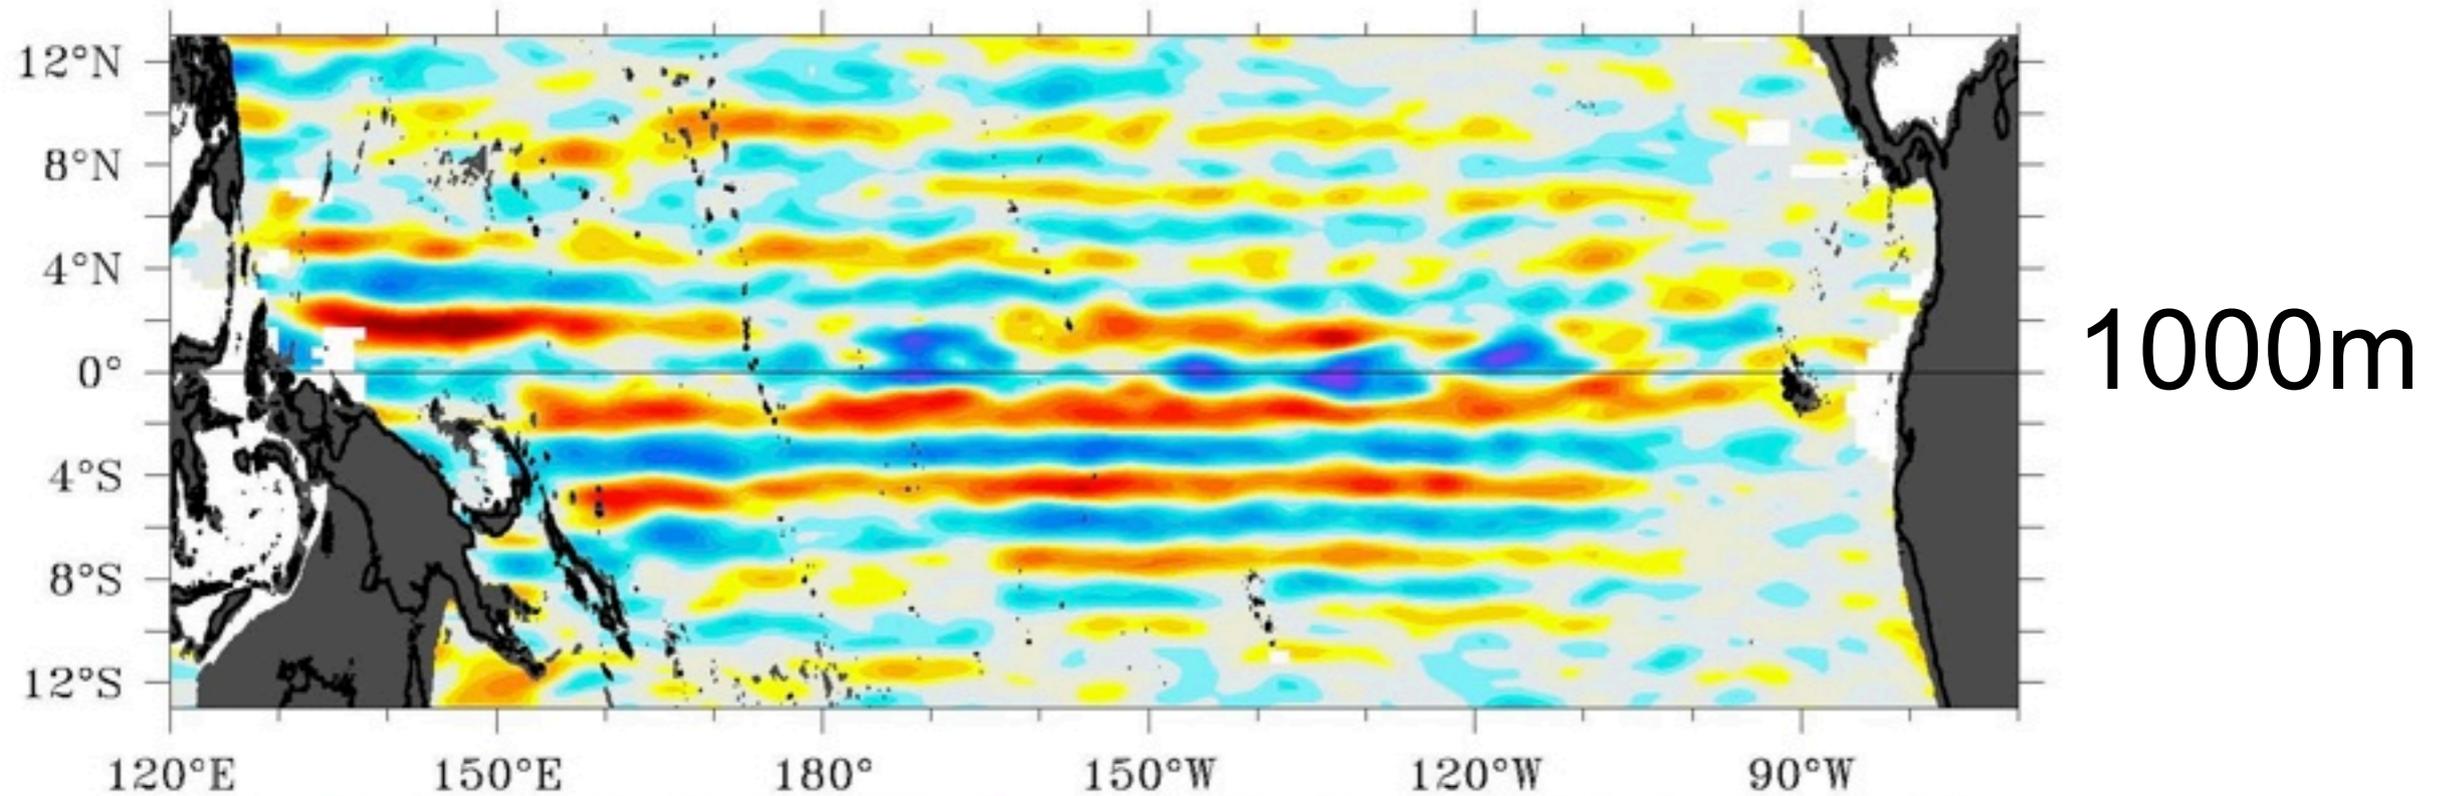

Subsurface advection (red arrow) can be estimated.

BUT:

This information is often missing.

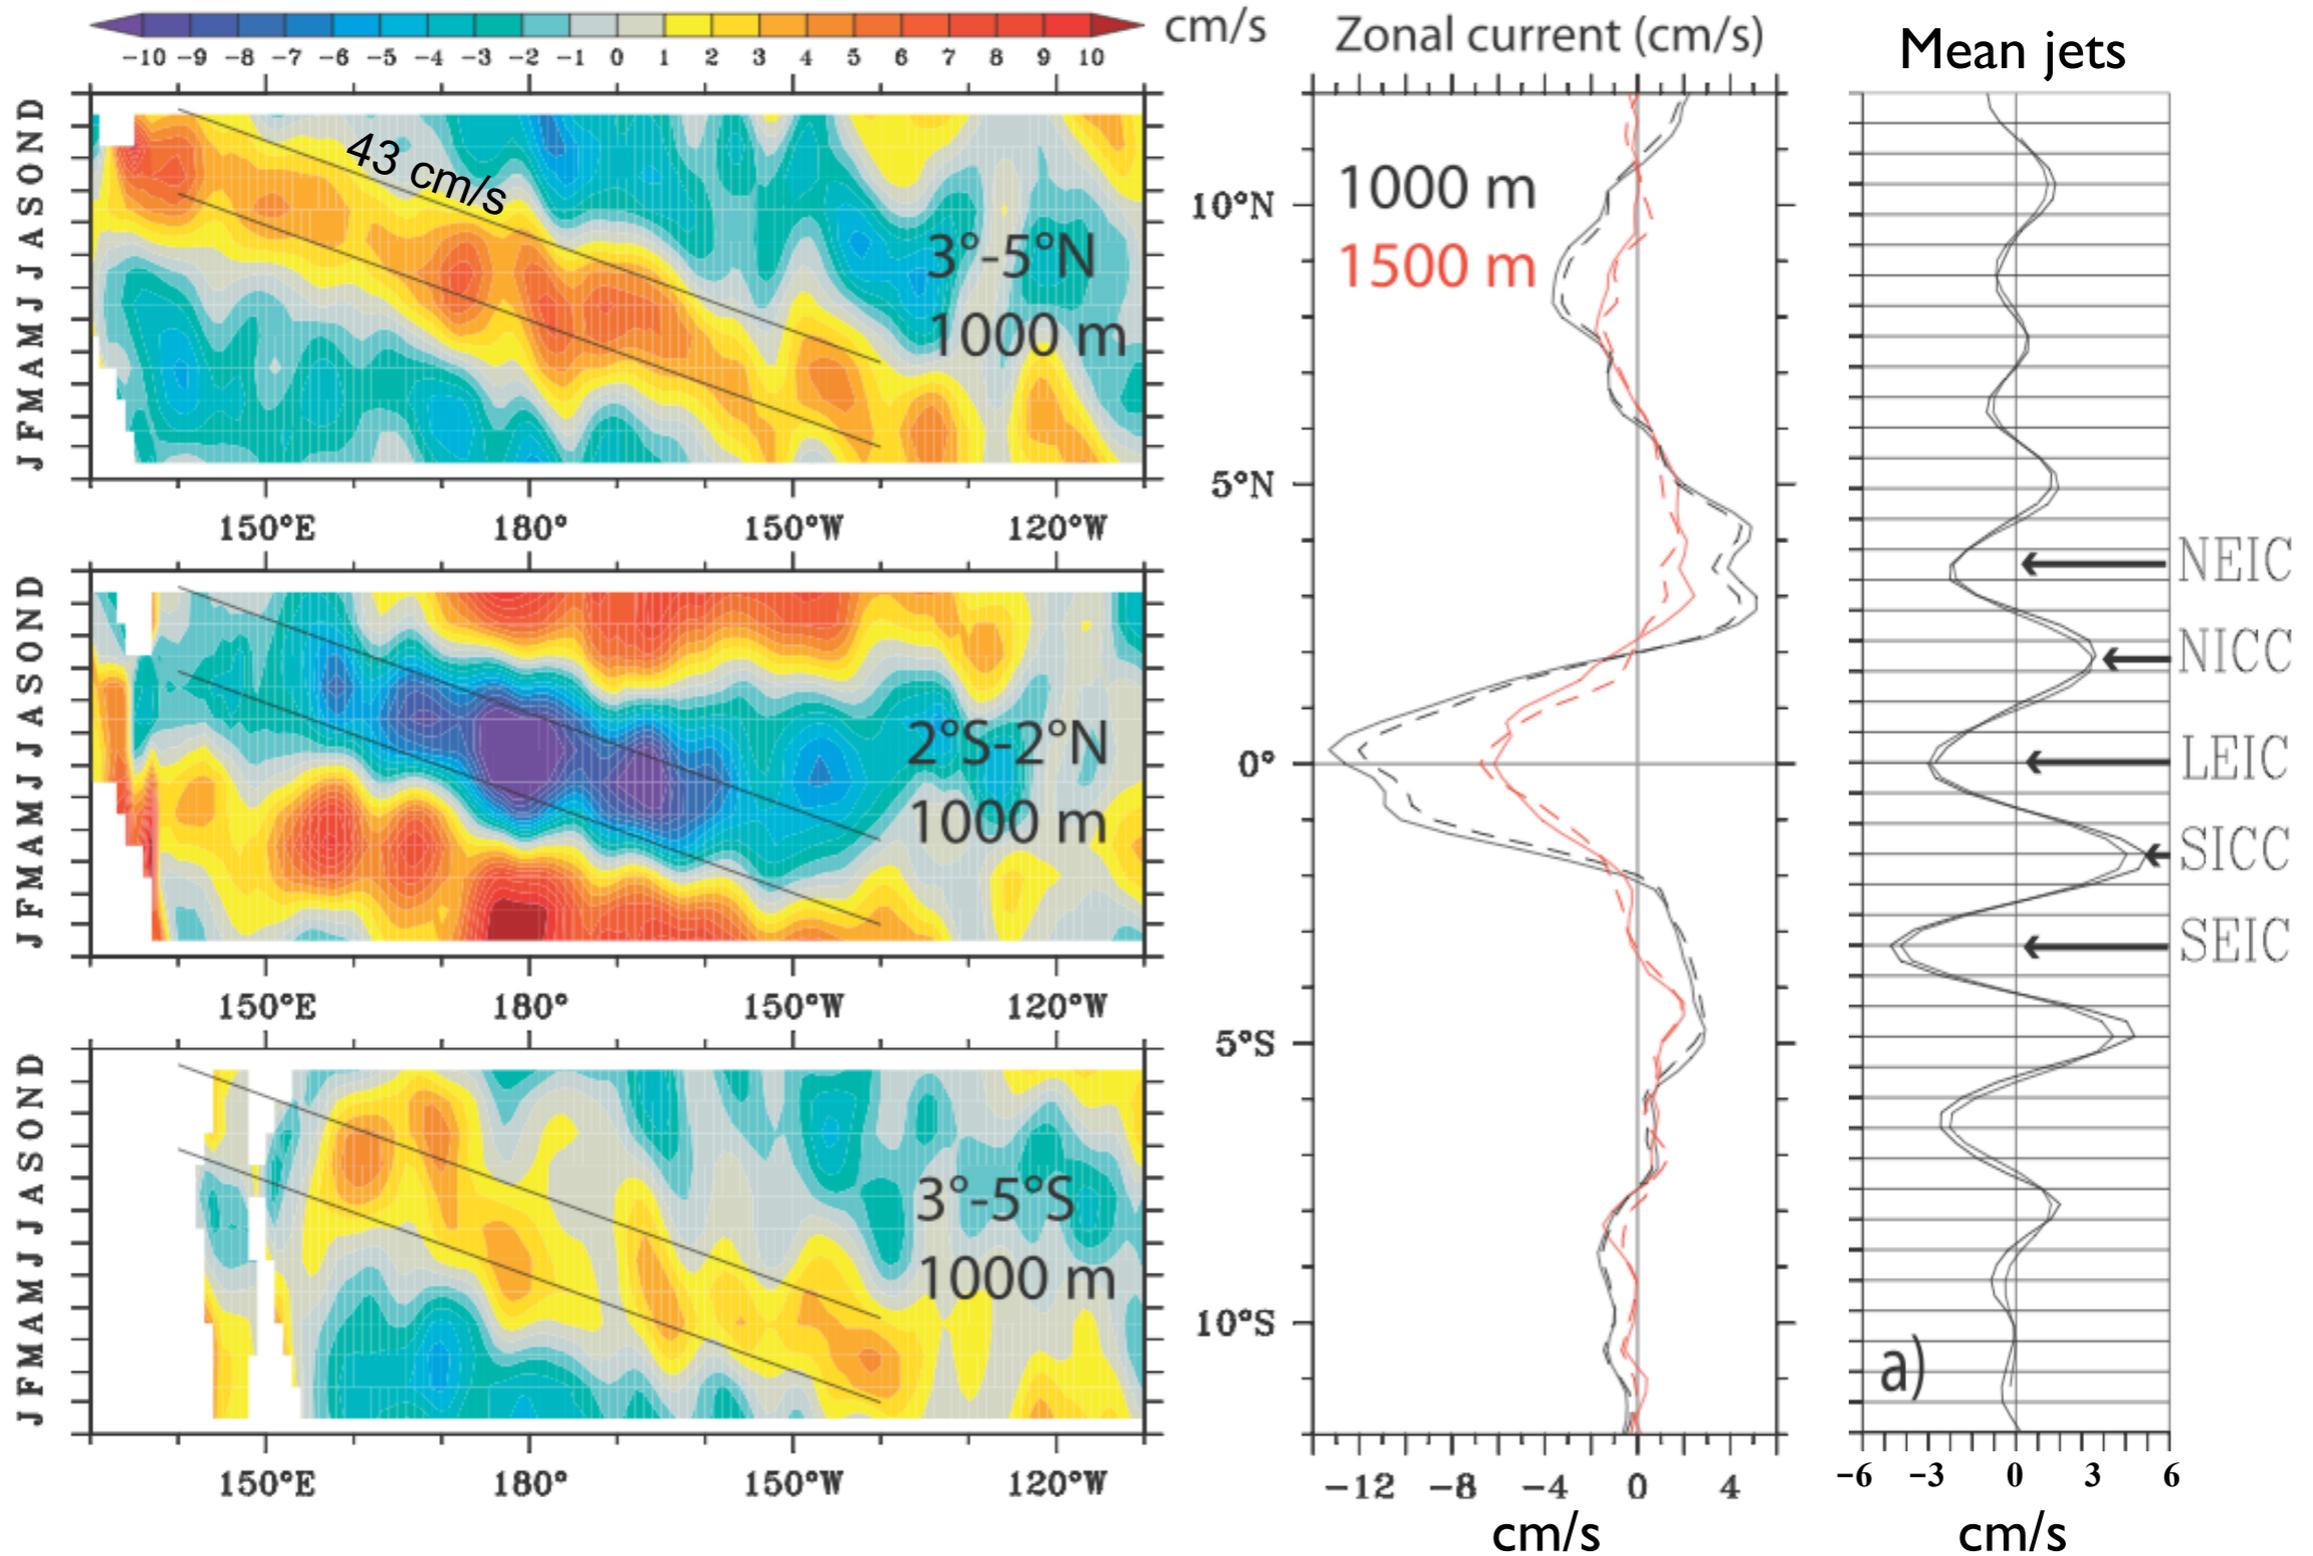

- 3 - Quality control (vital!): bad GPS hits, too-high speeds, grounding, ....  
many visual and statistical checks (about 87% of 107k values eventually accepted).  
Estimate median error  $\sim 0.4$  cm/s from unsampled motion during ascent and descent.

# Mapped $u$ at 1000 and 1500m

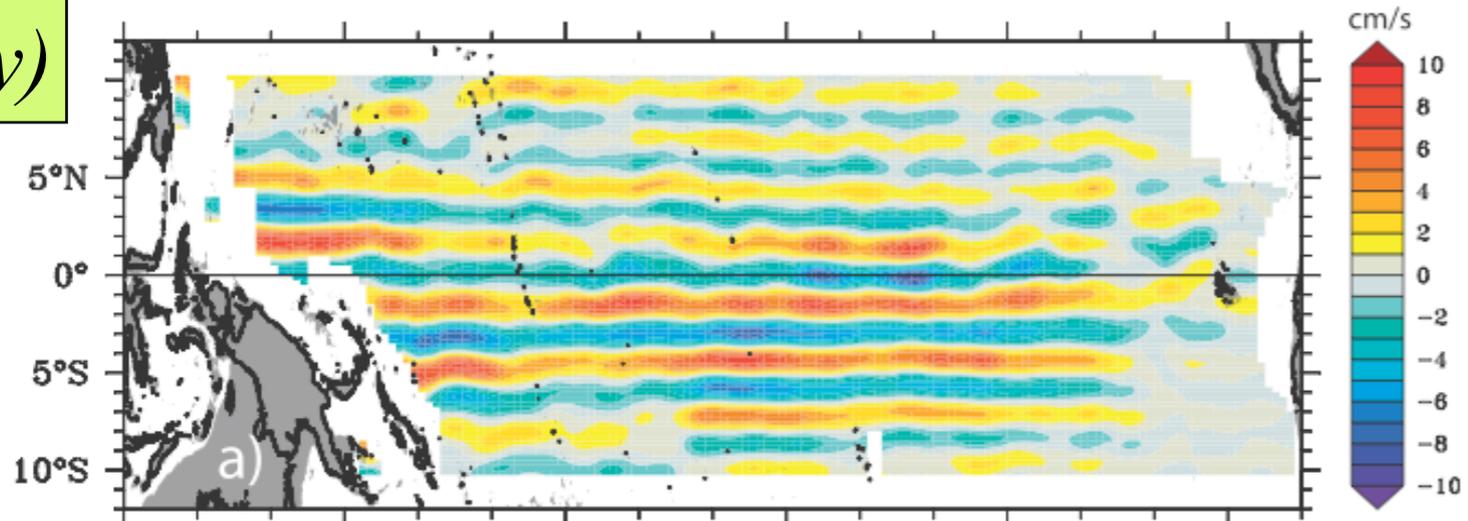

# Annual cycle of $u$ is the well-known vertically-propagating Mode 1 Rossby wave

- Annual propagation at same speed as found from earlier studies (of temperature variance)
- Annual cycle variance has different meridional structure from the background mean jets
- Large annual amplitude (implies jets can transiently “reverse”)

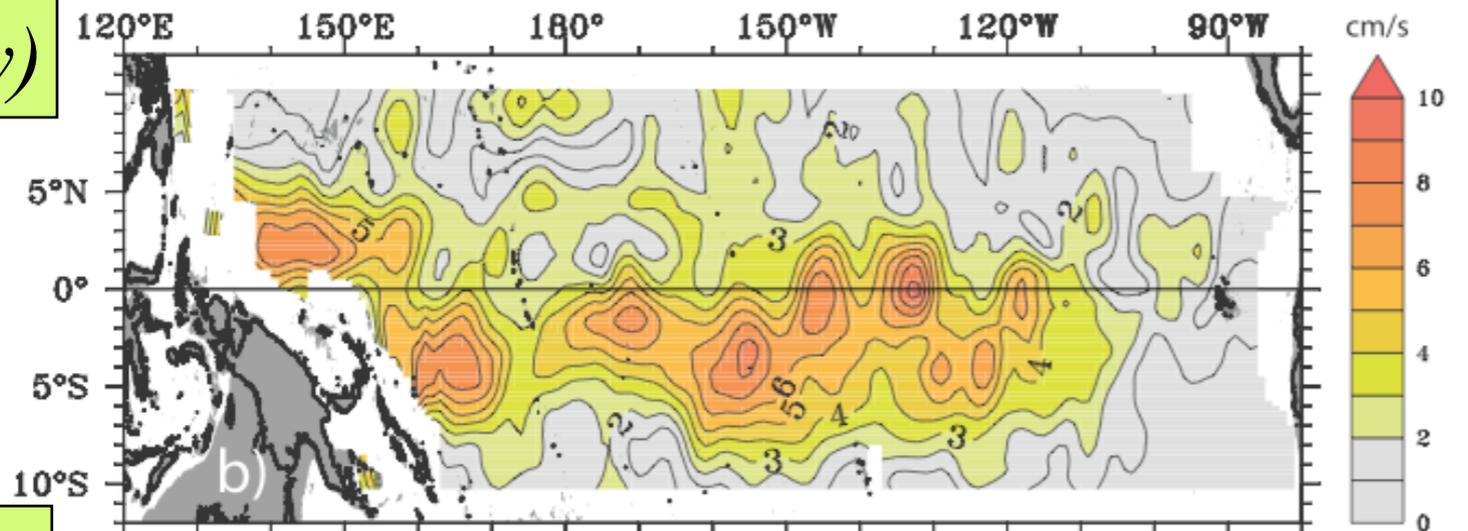

# Meridional scale: $\sim 300$ km between crests

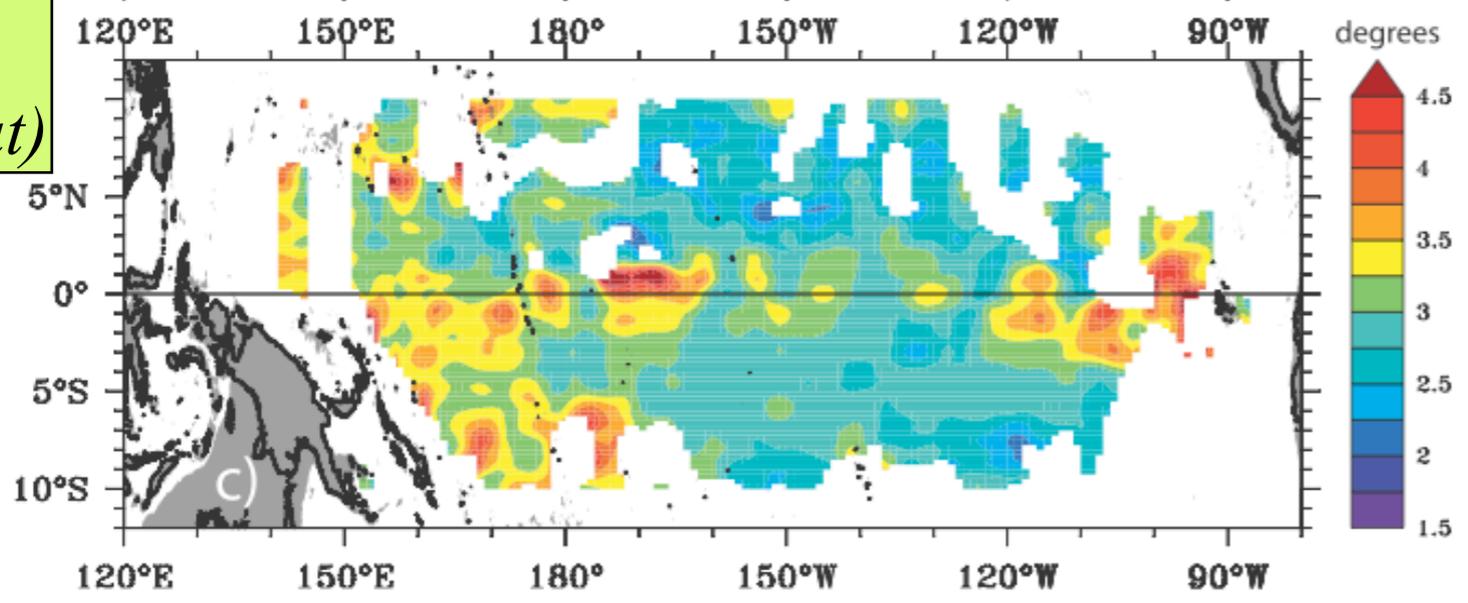

$u'(y)$

$A(y)$

$\lambda$   
(°lat)

Complex demodulation:  
→ LOCAL wavelength

$$u'(y) \sim A(y) \cos(ky + \phi(y)) + Z(y)$$

Initial guess for  $k$ ,

Solve for  $A(y)$  and  $\phi(y)$ .

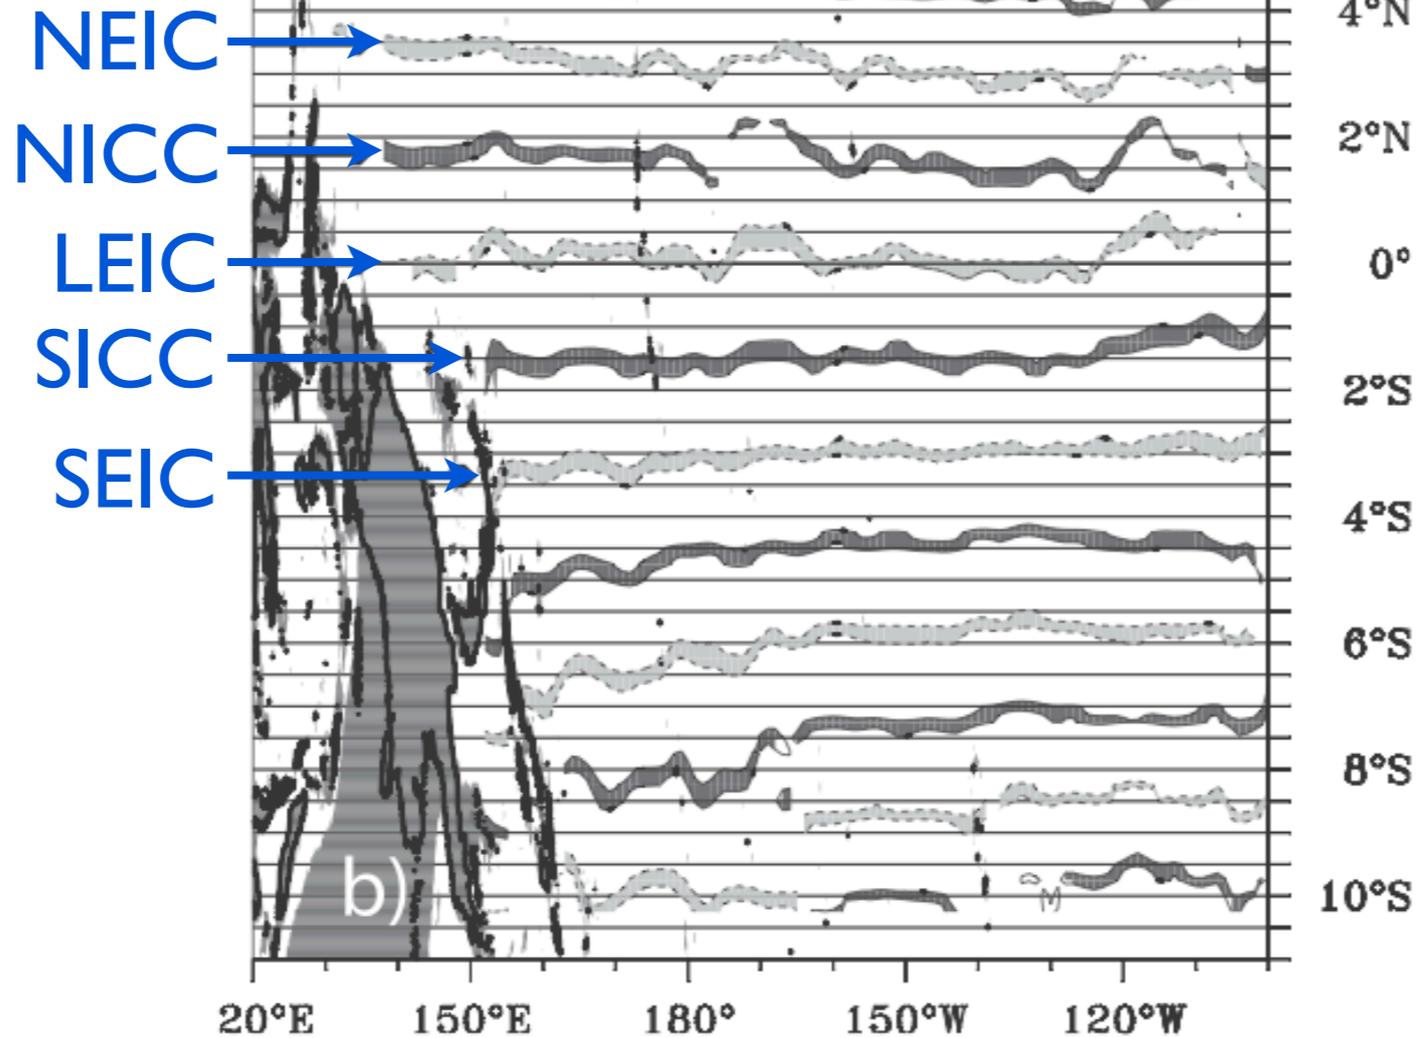

Interpret  $\phi(y)$  as a slowly-varying wavenumber modification.

- Results:
- Larger amplitude in the south (about  $\pm 5$  cm/s)
  - Meridional scale: about 300km (slightly larger in the west)
  - Slant poleward in the west

# Jets slant poleward in the west

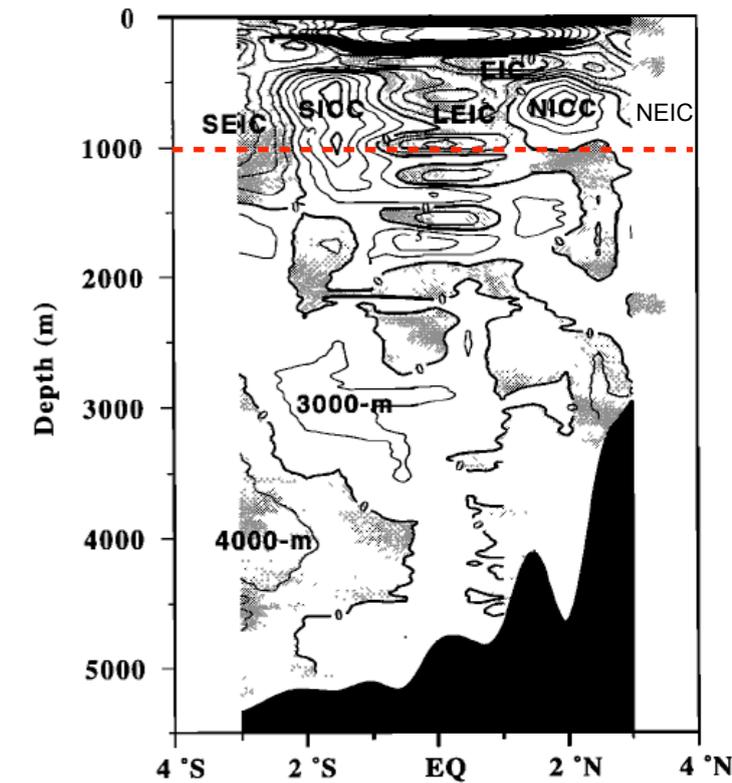

Eastward (dark) and westward (light) crests

If the pattern as a whole is a unit (I think it is), then naming the currents individually does not make sense.

(Firing et al. 1998)

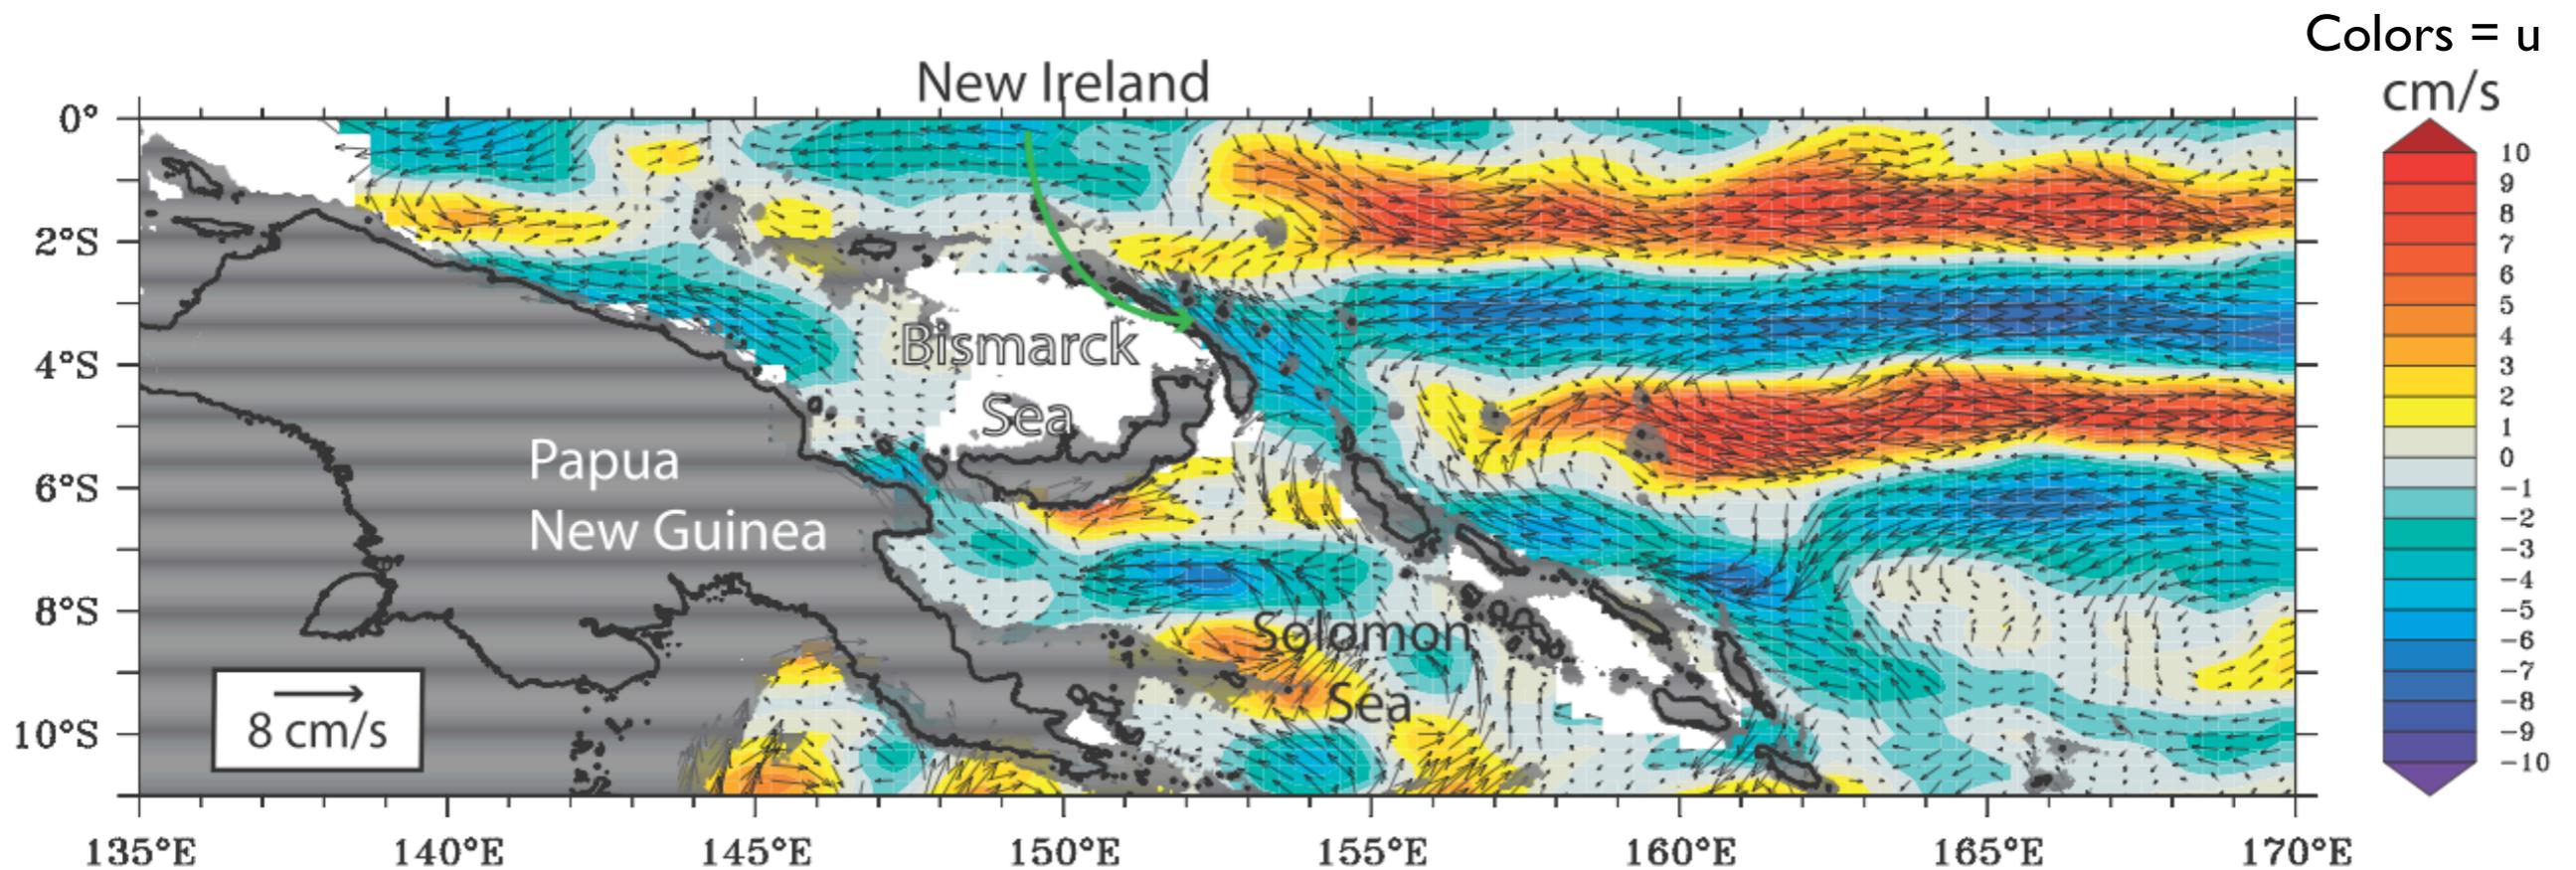

159° W (PEQUOD) 2/82 - 6/83

Northern jets shallower (why?). This might be why they appear weaker at 1000m.

# Jets arise close to the western boundary

They are connected by narrow western boundary currents

(Not enough data in the far western northern hemisphere )

# Ideas about “striations”

1)  $\beta$ -plume. A vorticity source (meridional flow past a topographic feature, or forced upwelling) generates a horizontal circulation much larger than the initial impulse. It produces a pair of opposite jets extending west. This is thought to be the origin of the striations seen in SSH west of California. (Maximenko)

Unlikely: No eastern source or features on the short meridional scale of the jets.

2) Rectified (dissipating), vertically-propagating equatorial waves (Ascani)  
Monthly-period Yanai waves break, Stokes drift rectifies into a true mean flow.

Unlikely (?): Would be confined to near the equator (3 jets).

Does not explain why the jets increase in speed to the west.

3) Sampling artifact of a train of eddies on a latitude line (Chelton)

Unlikely (?): Would need a generation mechanism for eddies on this merid. scale.

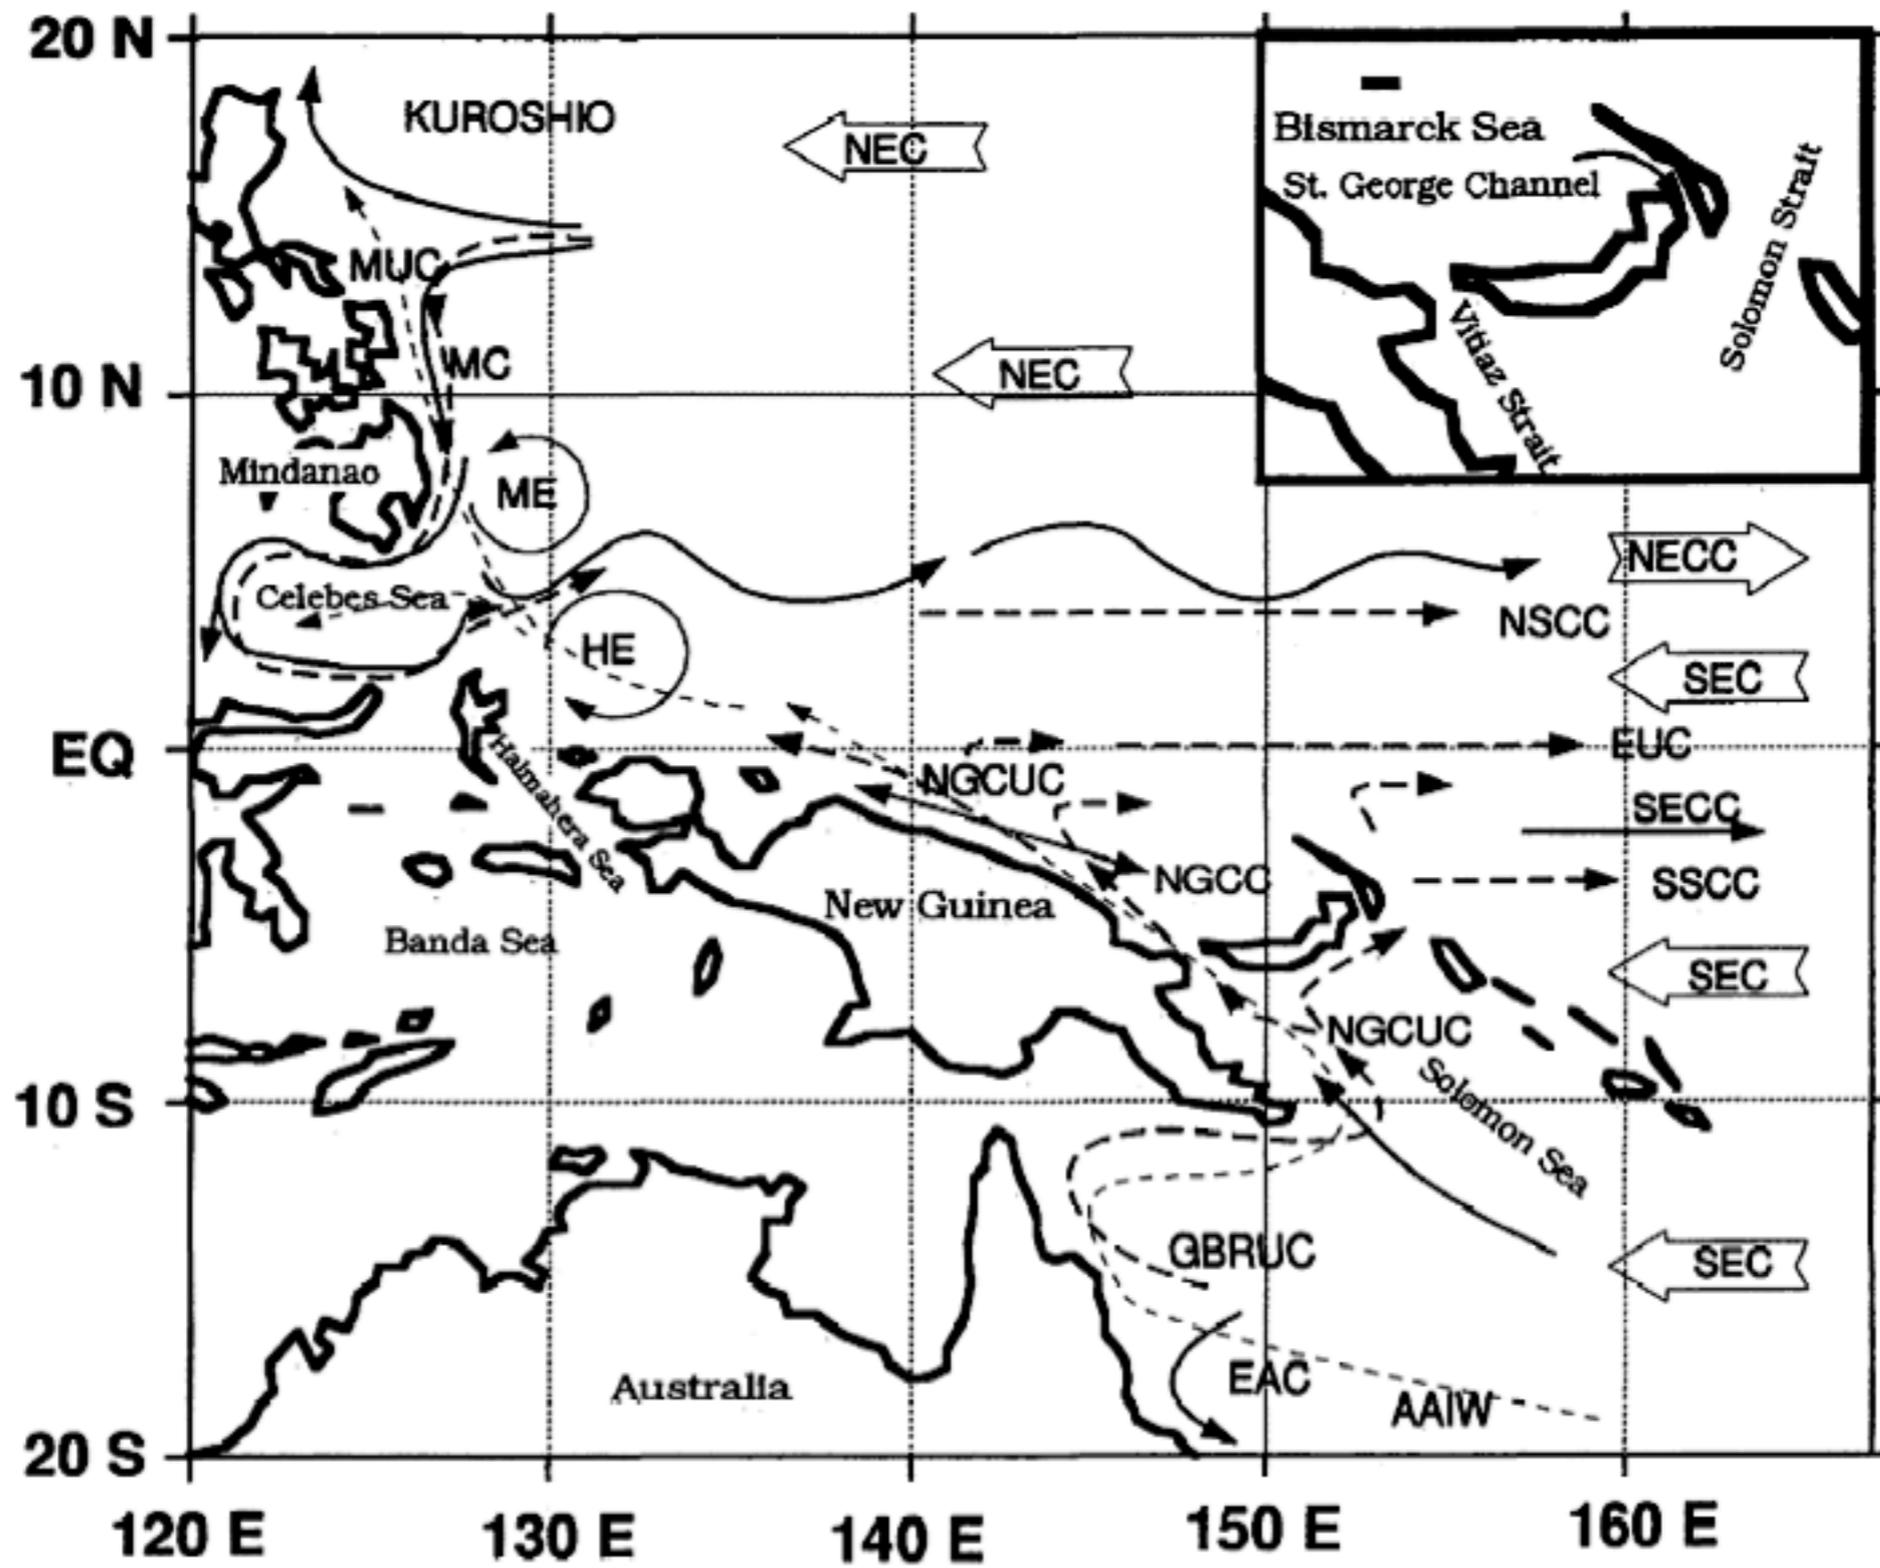

4) Self-advection of relative vorticity on the flanks of a forced jet. (Kessler/Moore)  
The EUC advects cyclonic  $\zeta$  on both sides eastward: increases both the initial jet and opposite-sign jets on both sides.

Unlikely (?): Hard to account for many reversals, does not explain western increase.

# Conclude

- Gliders (4-6 RT/yr) sample the absolute transport through the Solomon Sea
  - Strong ENSO signal, mostly in the upper layer, lagged behind ENSO indices consistent with linear theories.
  - The NGCU core is deeper than the ENSO signal, and less variable.
- 
- Argo float trajectories are a useful source of mid-depth flow (much QC)
  - A zonal jet or striation pattern spans the tropical Pacific:
    - The jet region is broader than equatorial (at least  $20^\circ$  latitude)
    - The jets do not begin at the eastern boundary or topographic features
    - Crest to crest scale  $\sim 300\text{km}$ ;  
slant poleward in the west, stronger in the west (and south?)
    - We cannot detect time-dependence (about 6 years of data)
  - Present theories do not account for this unified pattern spanning this wide latitude range.

Extra  
figures  
below

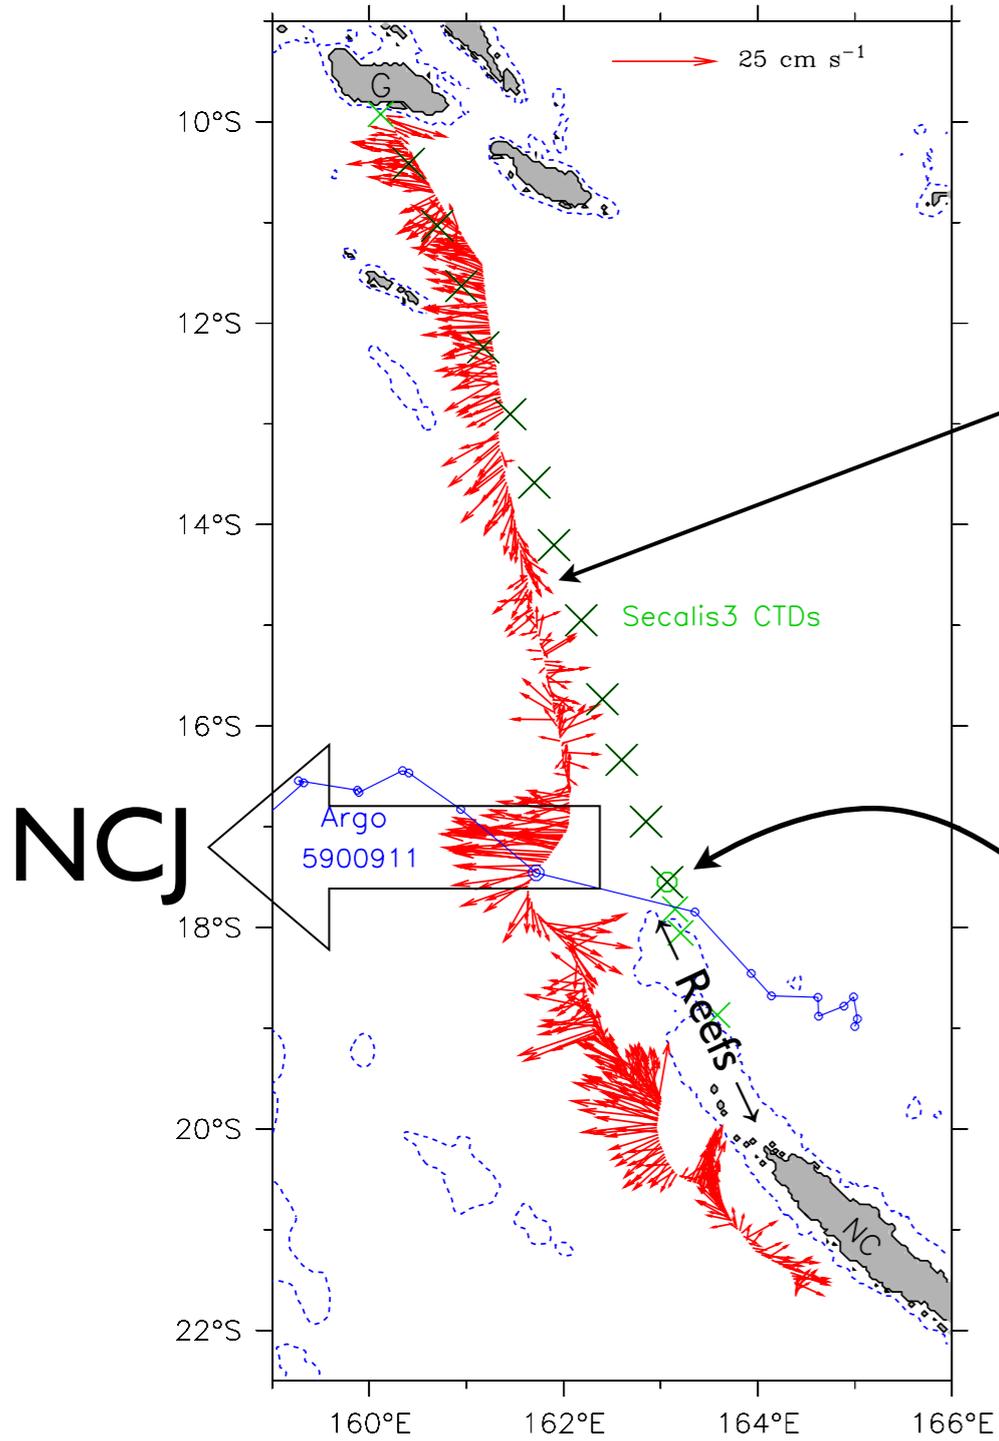

Fine et al., JGR 1994)

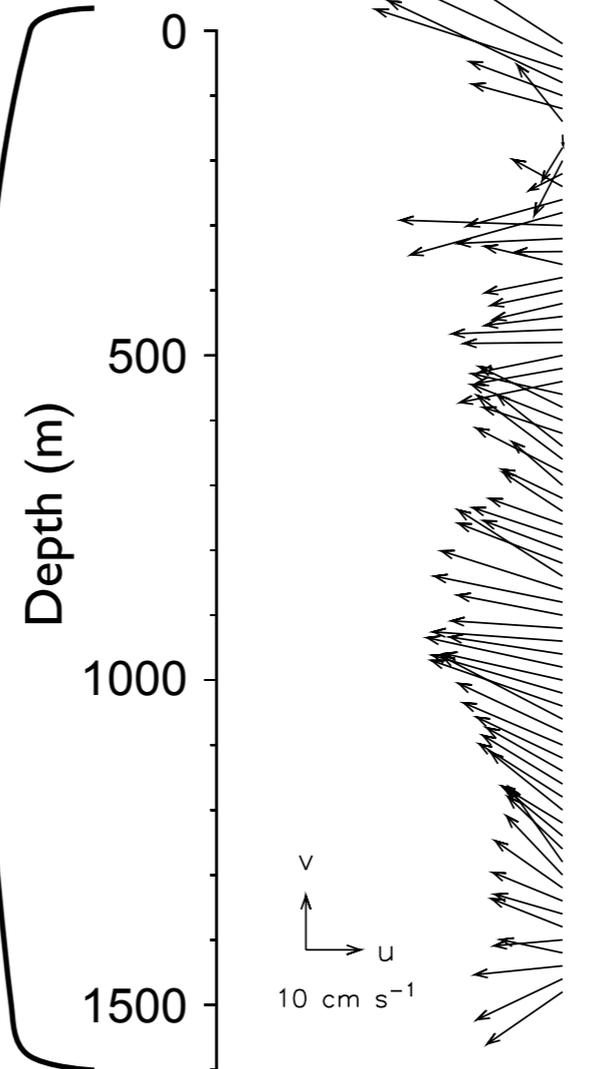

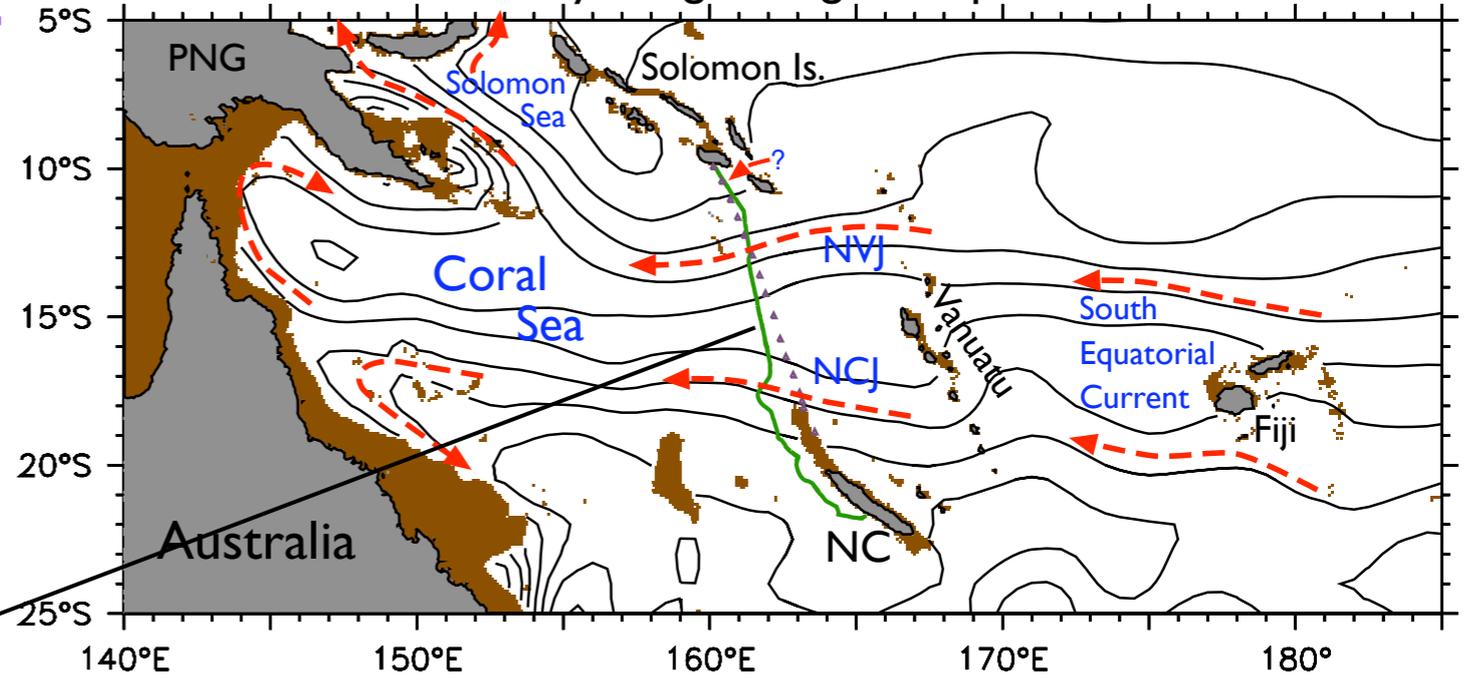

# The North Caledonian Jet

## precursor to the NGCU?

Gourdeau et al (2008)

CARS vertically-integrated geostrophic streamlines

**L-ADCP**  
 in the center  
 of the NCJ:  
 $u > 20 \text{ cm/s}$   
 to 1500+m

# Island Rule (Sverdrup) solution

- The islands affect the circulation two ways:
- Mountains block the wind, change the curl,
  - The islands block the currents.

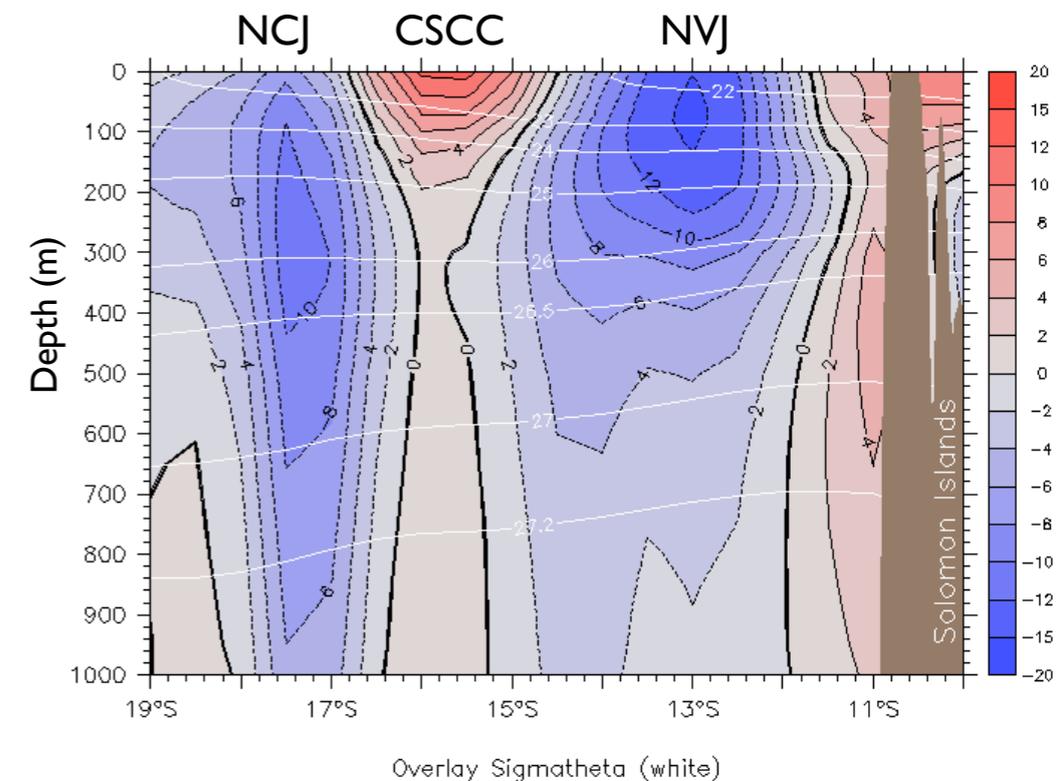

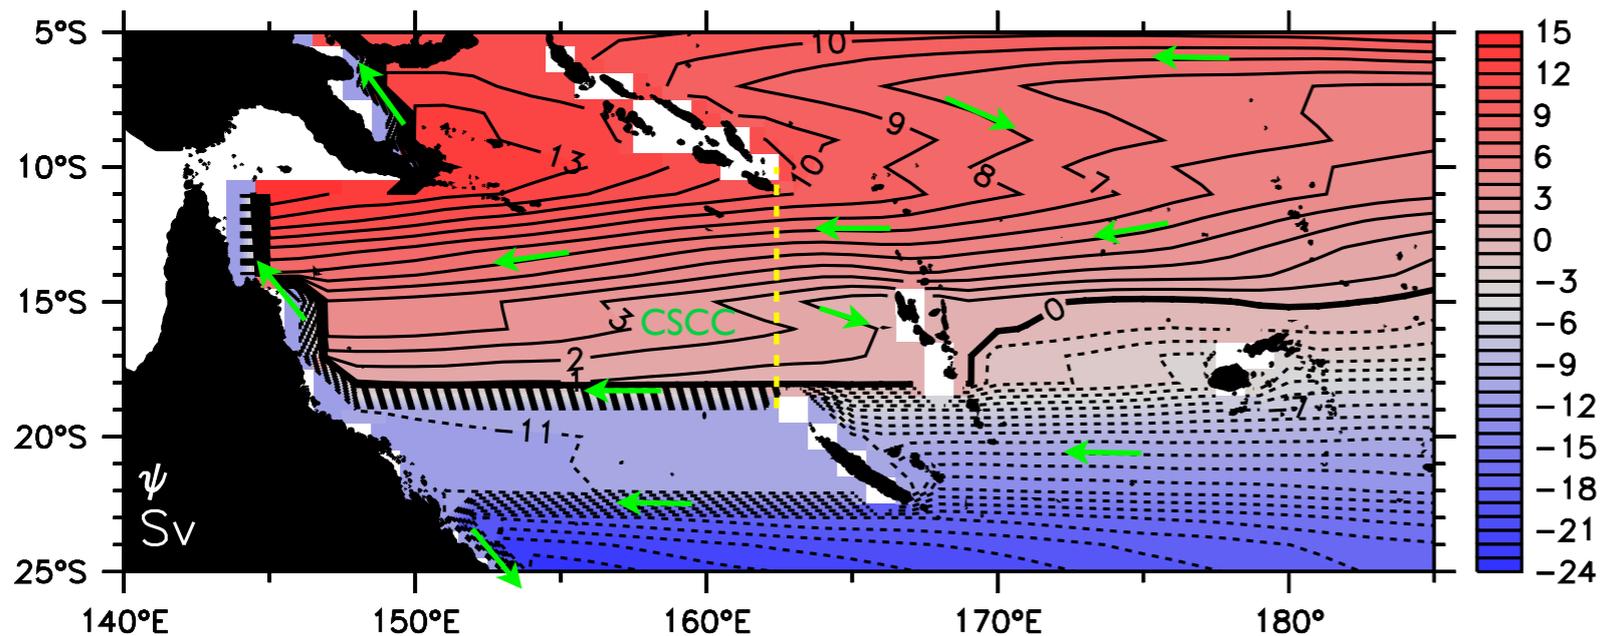

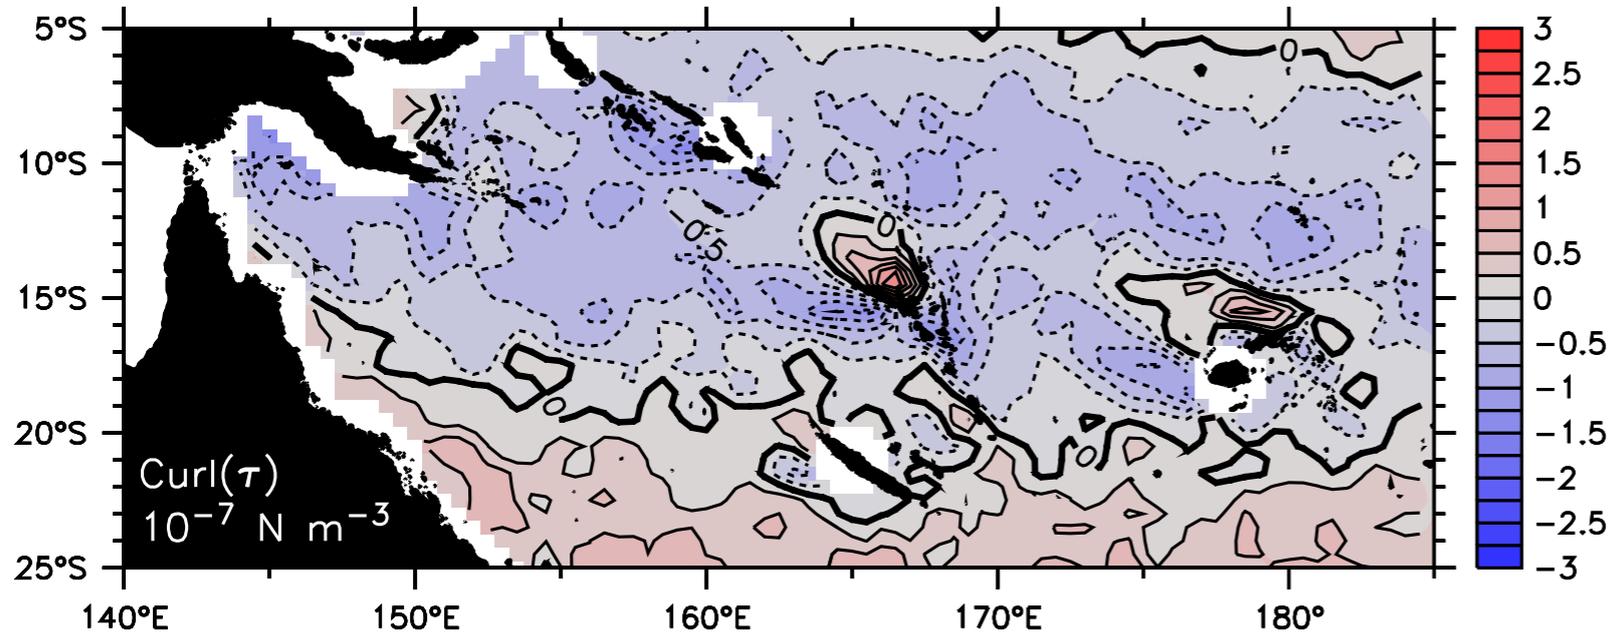

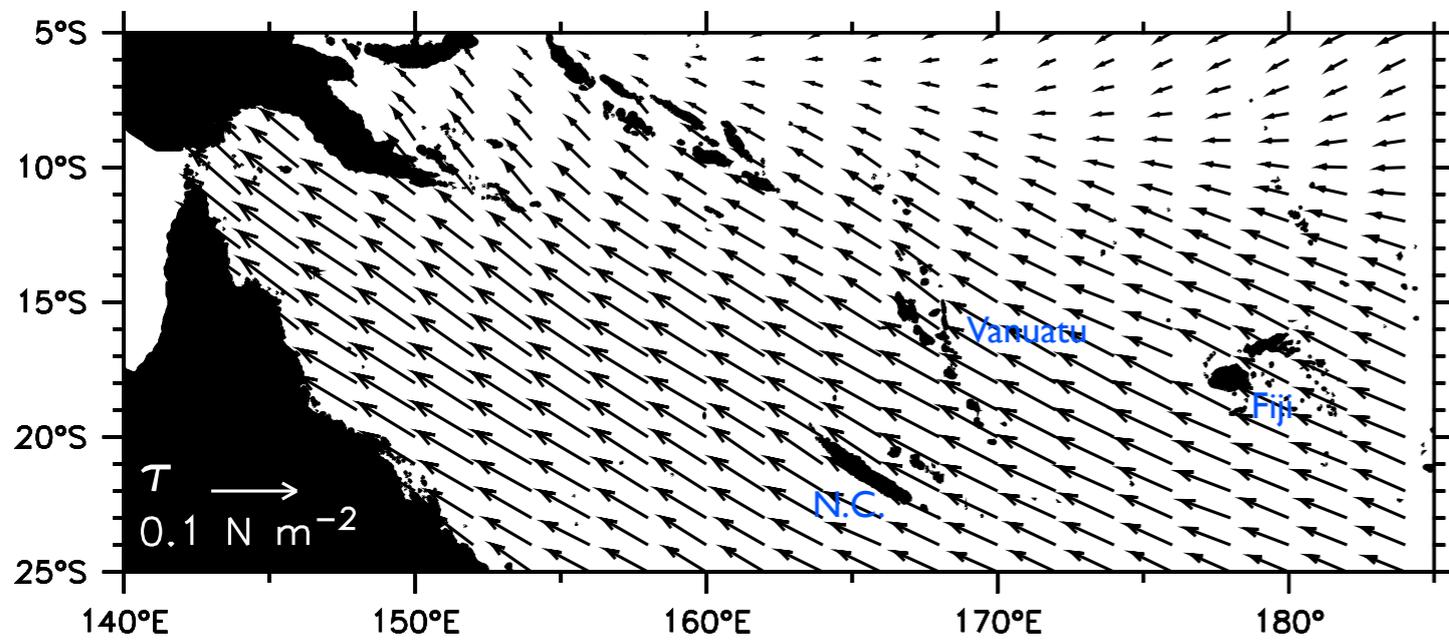

Two separate jets feed the Coral Sea:

S. Equatorial Cur. (broad current at 11°-14°S),  
=> slope of the main thermocline

N. Caledonian Jet (narrow jet at 18°S),  
=> shear only below ~600m

Curl around Vanuatu mountains produces  
Coral Sea Countercurrent (shallow)

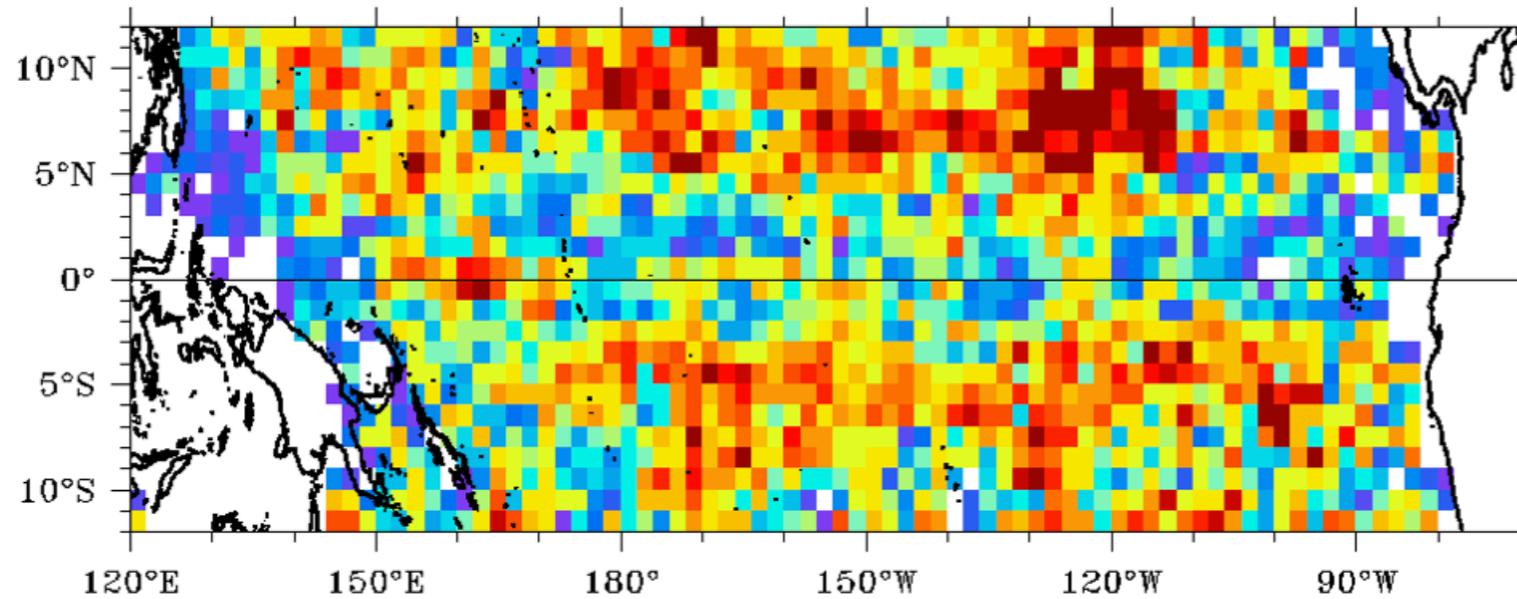

Mapped zonal current at 162.5°E

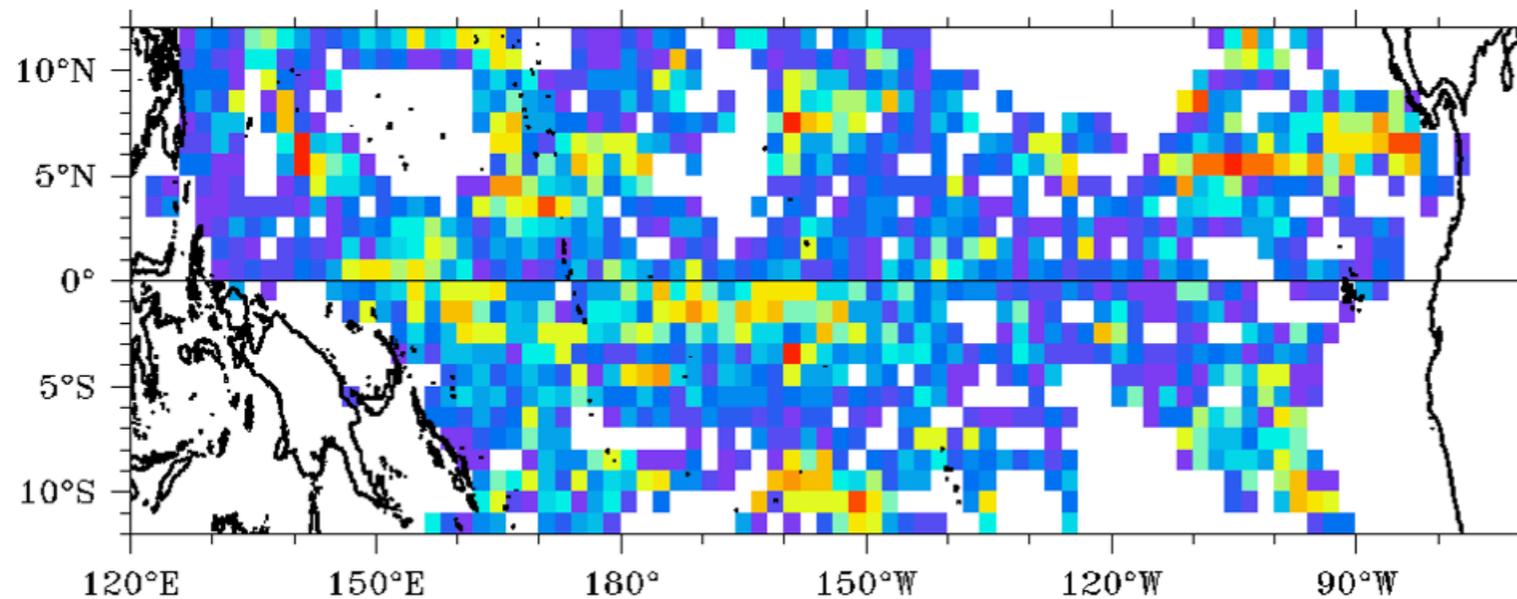

# Argo data distribution

Number of velocity values in  $2^\circ \times 1^\circ$  boxes  
January 2003-August 2011

→ What is the connection between these two?

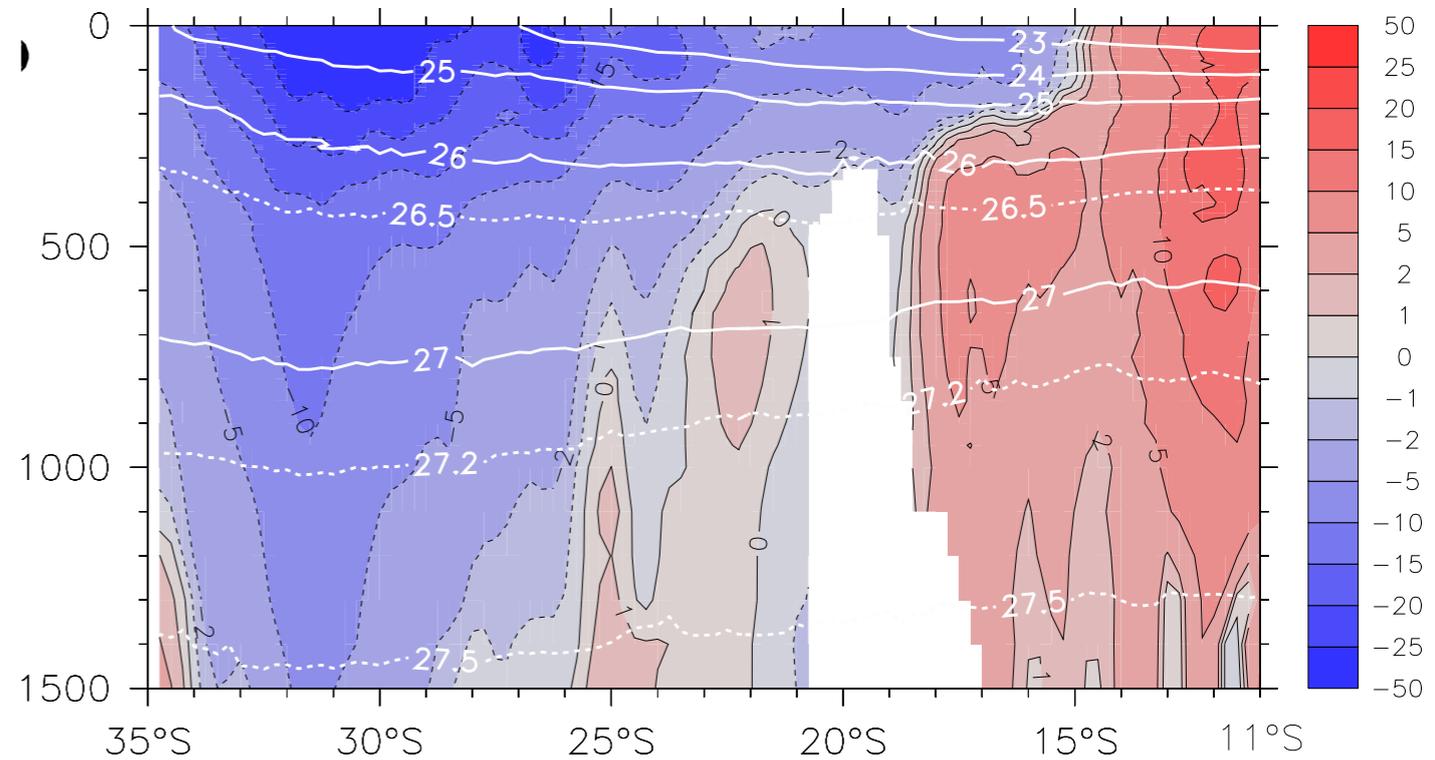

# Tilted subtropical gyre, tilted WBC bifurcation

175°W: Mean zonal current (color)  
and temperature (green contours)  
→ SubTropical CounterCurrent ←

An independent estimate of climatological  
alongshore velocity along the coast of Australia

Kessler and Cravatte (2013)

The bowl of the gyre tilts:  
westward shear below,  
eastward shear above.

CARS climatology (Ridgway & Dunn 2003)

→ What is the connection between these two?

# Conserve mass in western boundary layer.

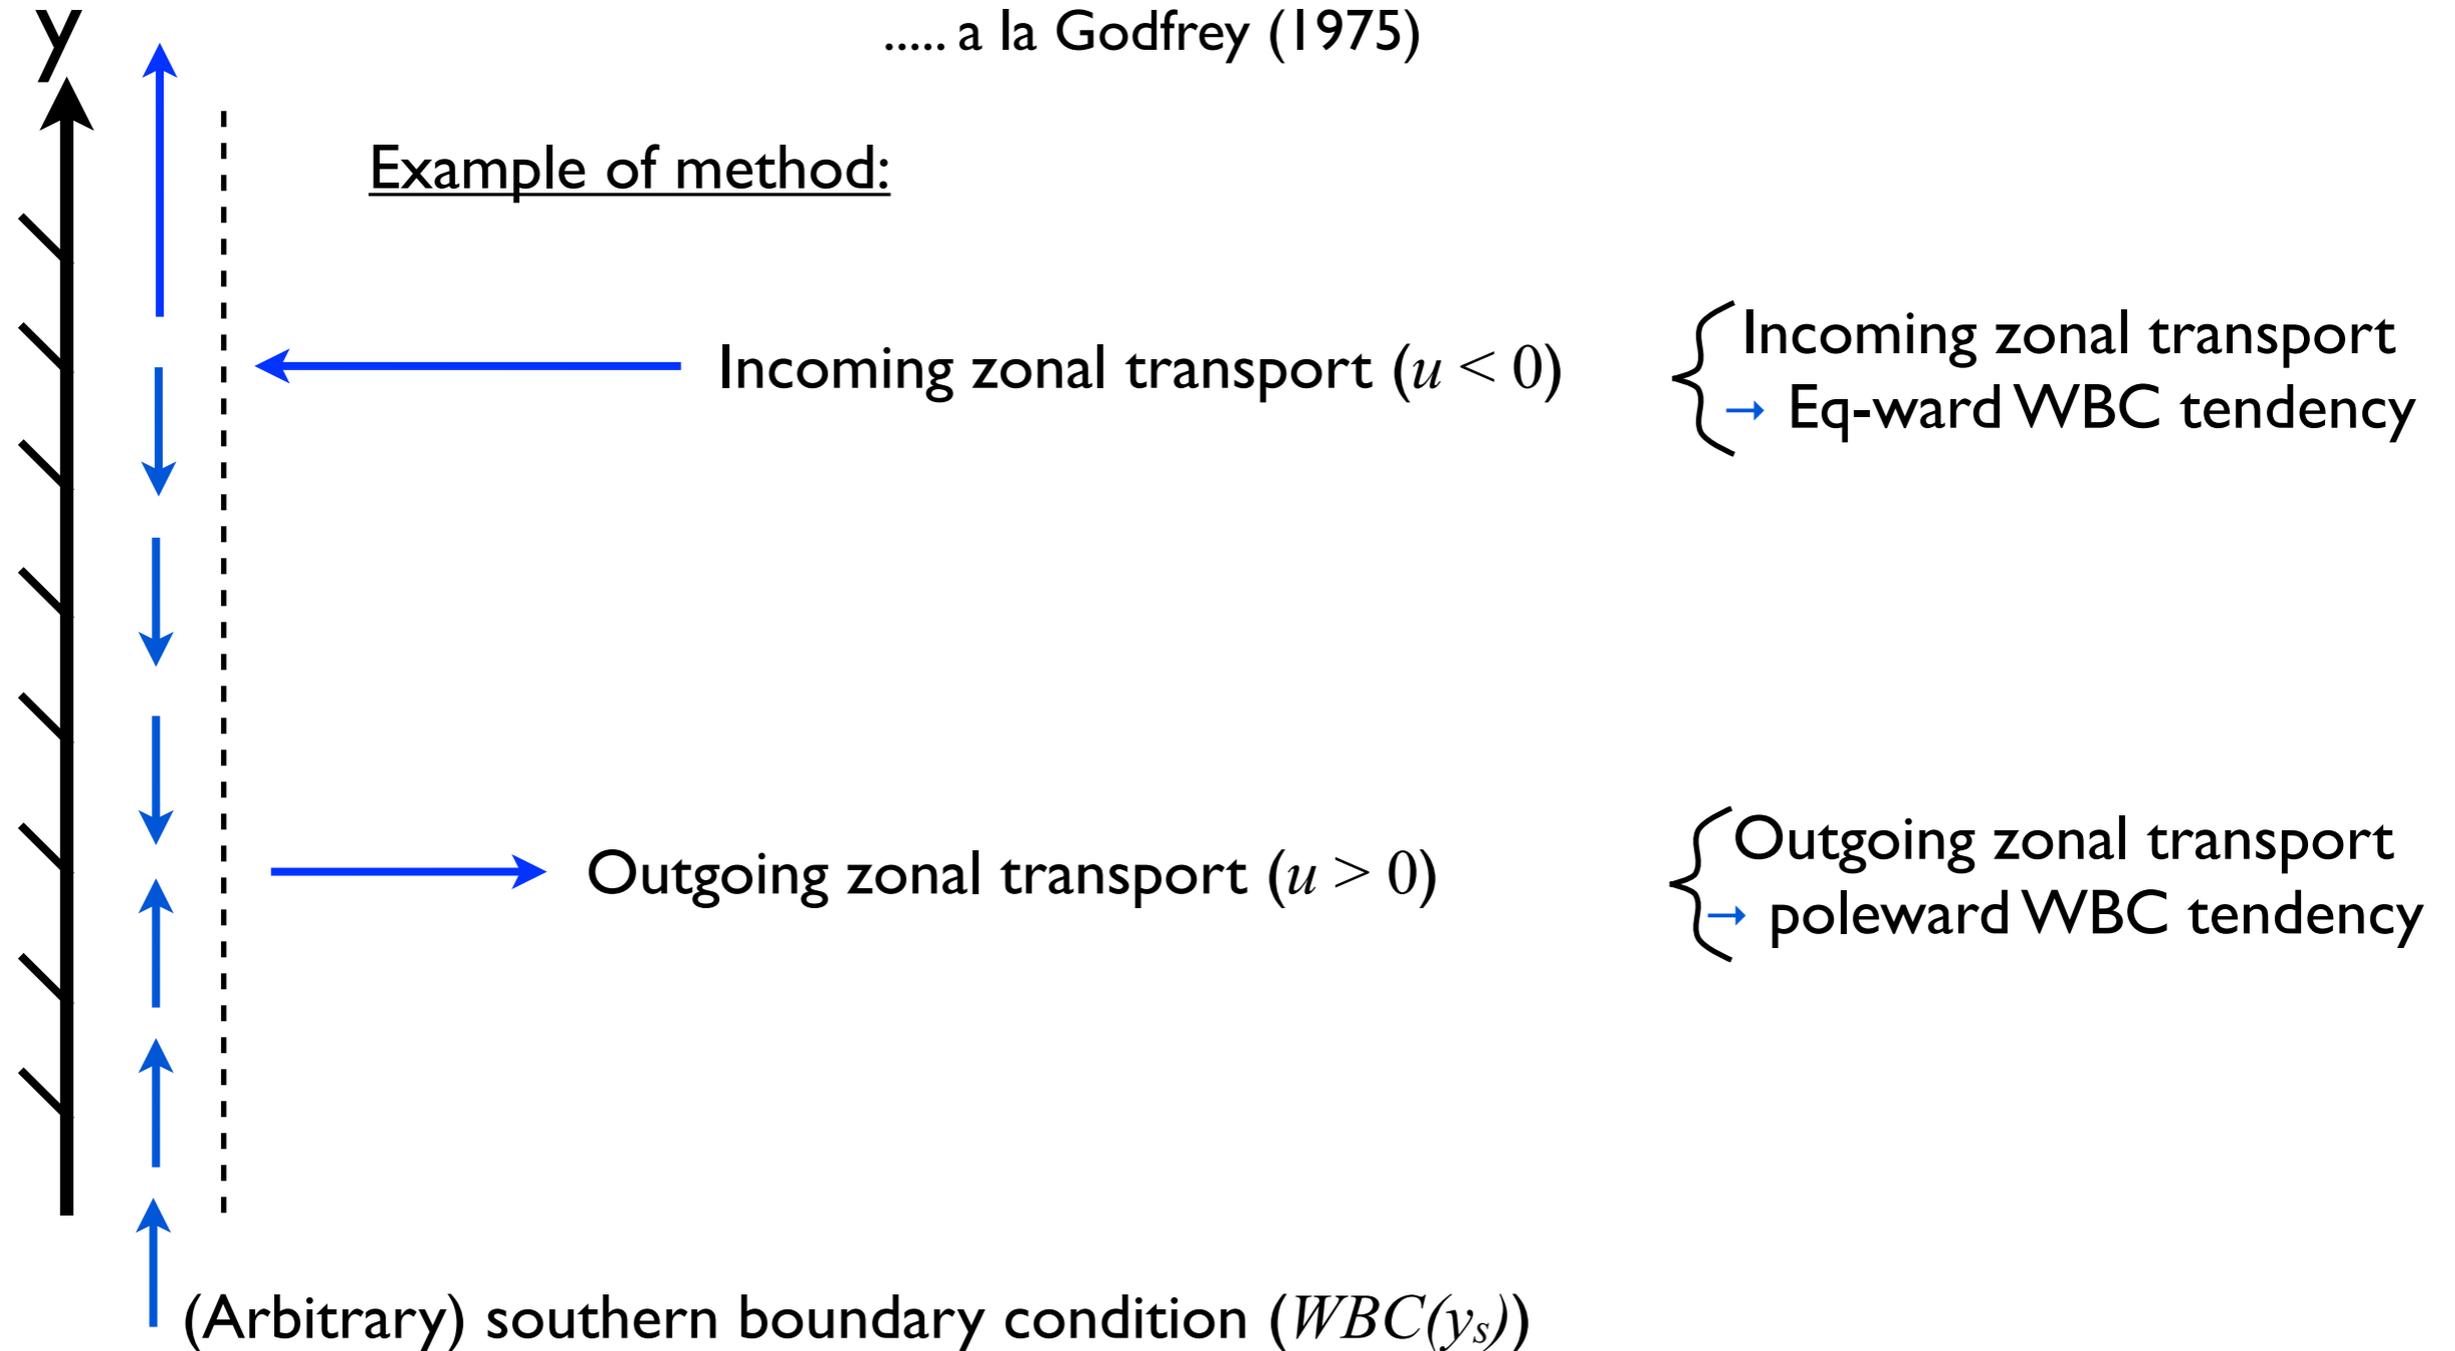

→ WBC is equatorward integral of incoming/outgoing transport.

$$WBC(y) = WBC(y_s) - \int_{y_s}^y u_g dy'$$

The WBC integrates the incoming zonal transport equatorward (because information travels equatorward on a western boundary).  
Need a southern boundary condition:  $WBC(y_s)$ .

..... a la Godfrey (1975)

Example of method:

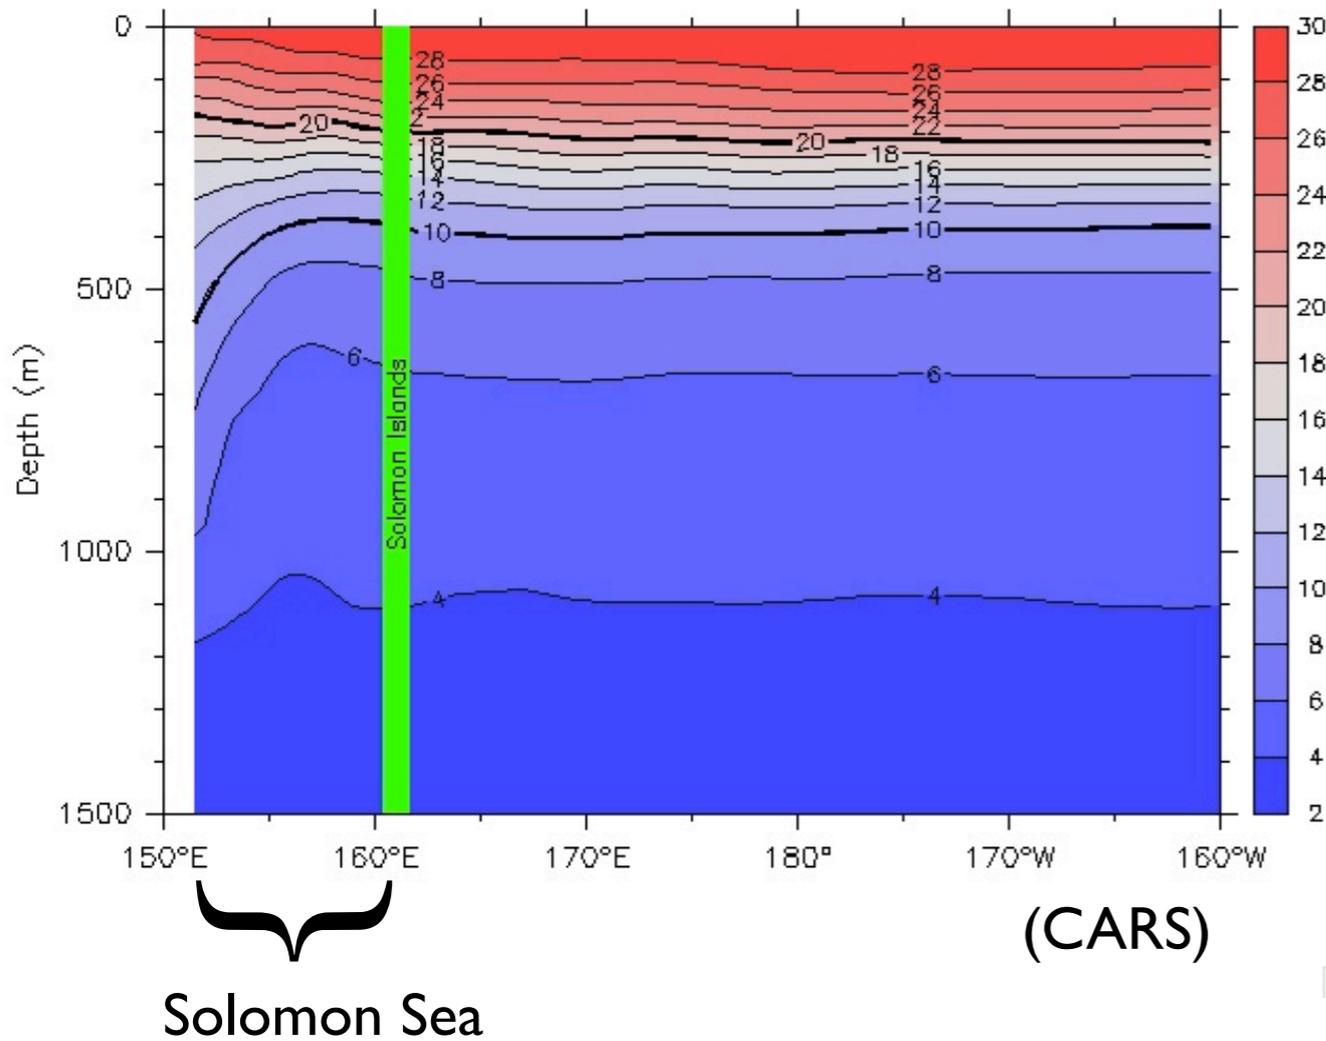

# Isotherm spreading at western boundary

## Poleward shear above NGCU: Undercurrent

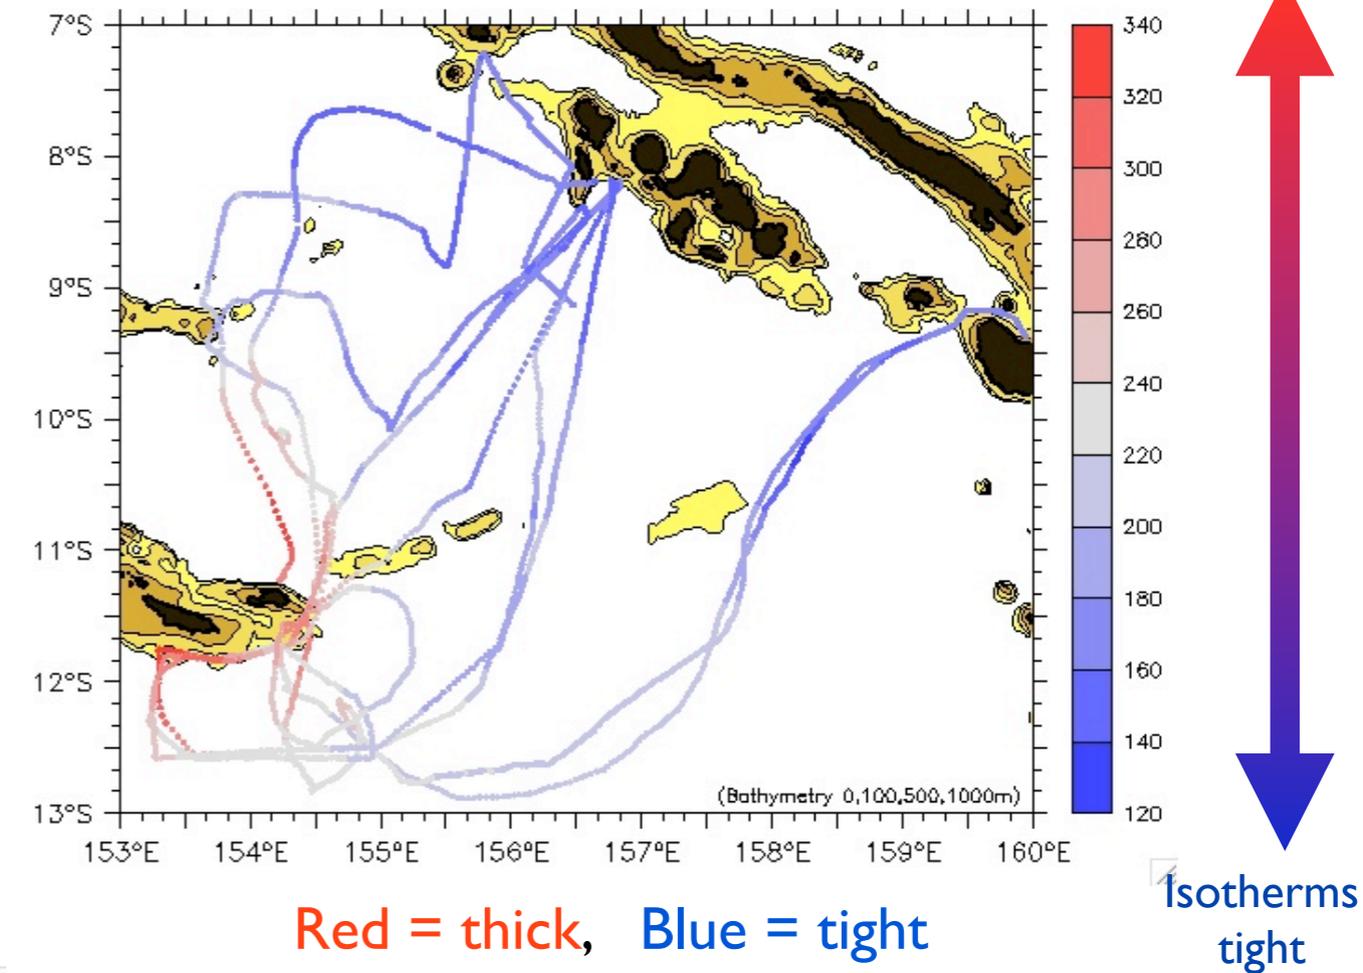

### Climatological temperature at 10°S

(Note: this analysis interpolated across the Solomon Islands)

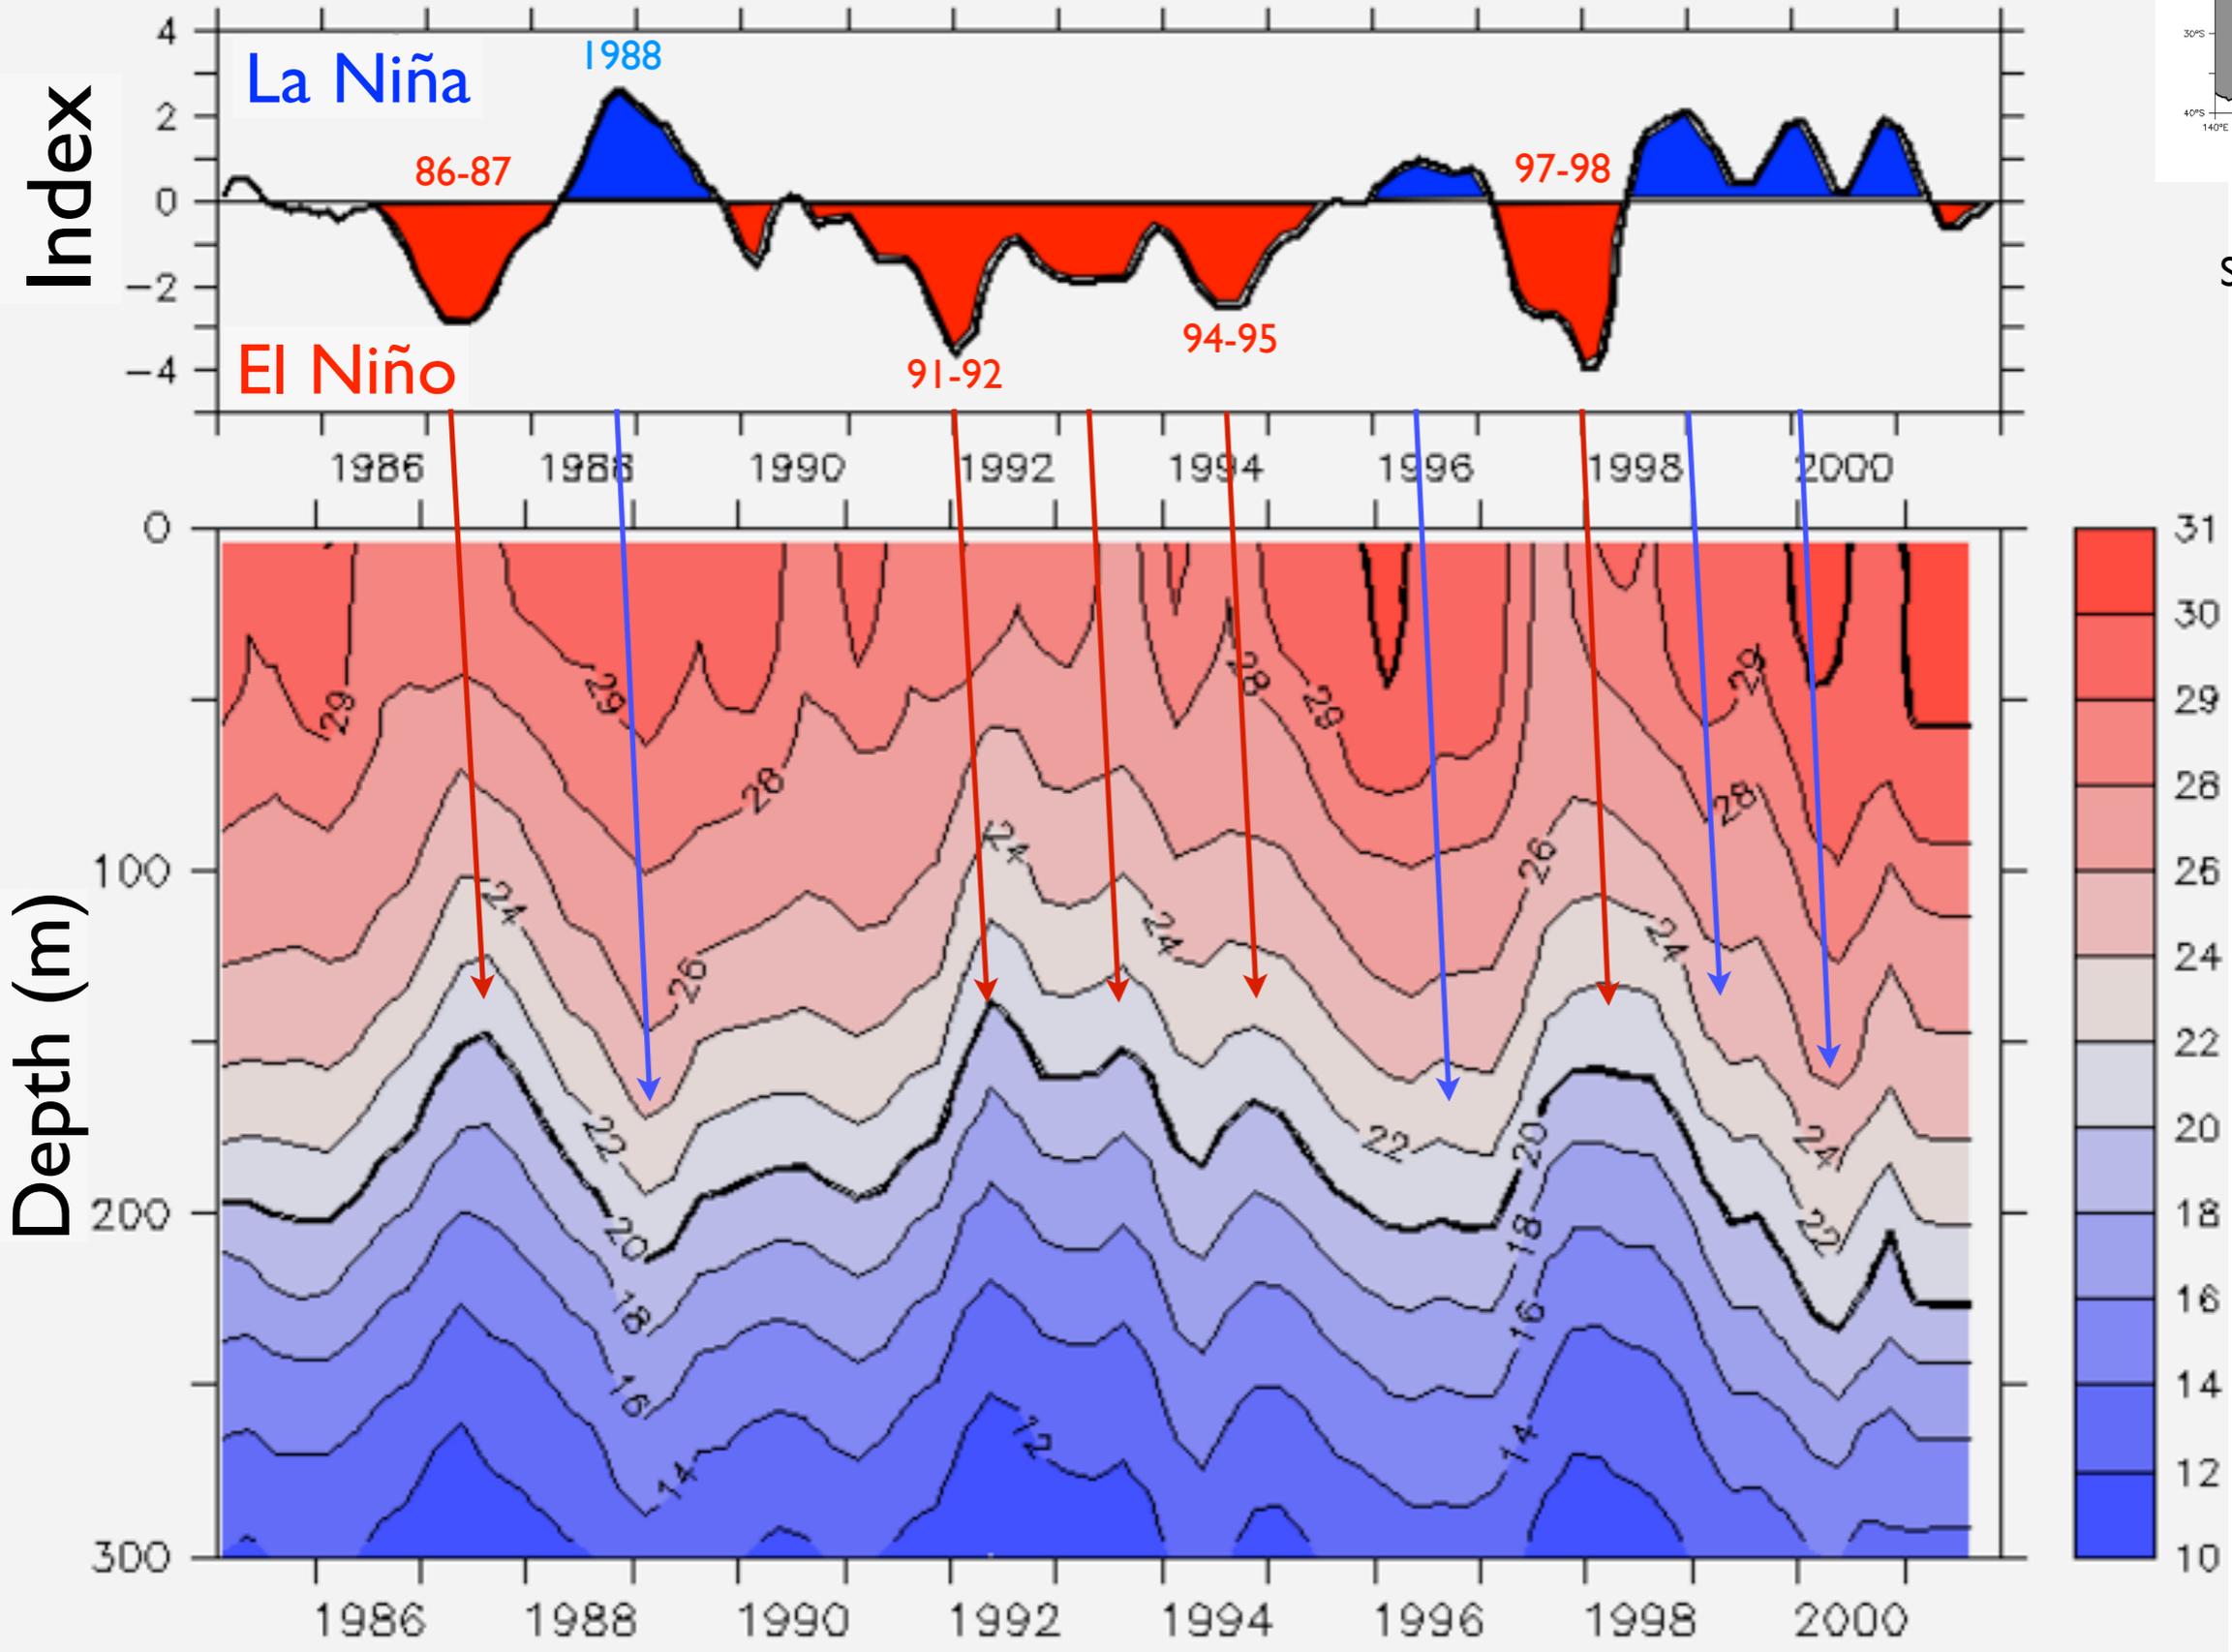

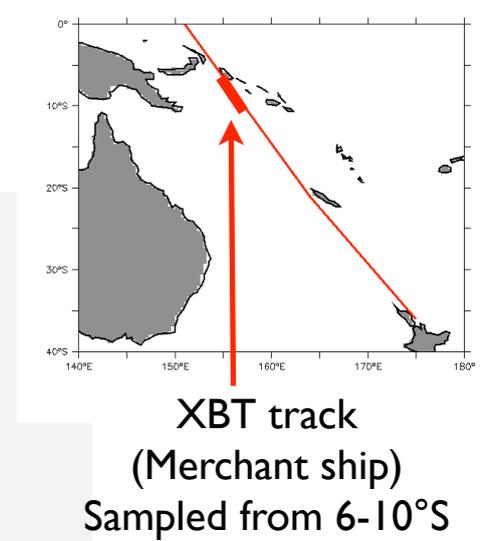

### 10°-20°C thickness (glider)
